- In fossil remains of the brain of *Homo rudolfensis*, signs of the Broca and Wernicke areas—control centers of speech motorics—have been identified. These areas in the left hemisphere of the human brain are responsible for the production of linguistic sounds as well as for the comprehension of speech.
- The hypoglossal canal through which nerves are transported is linked to the tongue, which is the most essential organ for the articulation of the sounds of human speech. The size of this canal is much bigger in humans than in early hominids or non-hominid species.
- The vocal tract has a unique position in the anatomy of humans and is different from other mammal species. In mature humans, the larynx lies lower in the neck. This increases the size of the pharynx and enhances sound production. In infants and

in all other mammals, the position of the vocal tract is high. This enables the individual to breathe and swallow at the same time (which is impossible for adult humans) but reduces the scope of vocalization.

Australopithecines, as one primate branch with several subspecies (*ramidus*, *africanus*, *robustus*), appeared more than four million years ago. This is the last common ancestor of all hominid species. The vocal tract of australopithecines is similar to that of chimpanzees and is incapable of producing the sounds necessary for human speech. None of the other indications of the capacity of speech and the faculty of language mentioned above can be identified for this species since the *Australopithecus* brain was similar to an ape's.

The Advent of Speech in Human Evolution

Language is a system of signs used to communicate symbolic meanings. Although linguistic ability is clearly an aspect of being human, did it develop suddenly with the appearance of *Homo sapiens sapiens*, or did the ability to speak evolve slowly as an attribute of other hominid species?

It is possible, of course, to communicate without the use of articulated sounds. Meaning can be expressed by the use of visual signs, by symbols of a gestural code (as in sign language), or in writing (via signs and graphic symbols that signify ideas or letters that represent the sounds of speech).

Behavioral scientists have carried out extensive experiments with chimpanzees, orangutans, and other primate species to understand their capacities to use signs and symbols. Research findings indicate that nonhominid primates possess astounding abilities to learn human language by means of gestures and to identify letter se-

quences within a written code. This speaks in favor of a long evolutionary history of symbol making. And yet the capacity for symbolic activity in nonhominid species remains latent and seemingly unexploited in their natural habitats. The ecological conditions of life for primates do not require the use of complex sign systems such as language.

Although the ability of primates to recognize symbols may go back more than 7 million years, the capacity to produce the sounds of human language can only be traced to the emergence of our own species between 120,000 and 150,000 years ago. The relationship between the sound structure and the meaning of words is arbitrary in complex human language. The fact that English “house,” Italian *casa*, Russian *dom*, Finnish *talo*, and Japanese *uchi* all have the same meaning is a matter of convention within each local language. These conventions are perpetuated from one generation to the next through the process of language acquisition by which humans learn to articulate the sounds of speech and to group sounds into meaningful sequences. This is something primates cannot do because they lack the anatomical features to produce the sounds of human speech.

For several decades, paleontologists were convinced that archaic *Homo sapiens* (*Homo neanderthalensis*) had the faculty of language. The ability of Neanderthals to organize their living conditions and to construct the fabric of culture was rudimentary and lacked sophistication. It is widely assumed that their ability to communicate corresponds to the stage of protolanguage. What could not be answered with any certainty until recently was how many sounds of human speech the Neanderthals were capable of articulating.

Final proof for the presence of language among Neanderthals came in 1989 with the find of a hyoid bone (language bone) in a Neanderthal skeleton in the Near East. This bone, which lies between the root of the tongue and the larynx and is connected to their muscles, is known only in modern and archaic humans. The mere existence of this bone in archaic humans is evidence of their ability to produce sounds of speech. Therefore, the development of language (as a system of arbitrary signs) and of speech (as articulated in sounds) began with the Neanderthals.

How limited were the language skills of Neanderthals, and did their language represent a fully developed sign system? Moreover, did the complex linguistic ability of modern humans emerge out of a leap in evolution, or were there stadial differences in the transition from Neanderthals to our species? Were there archaic stages of development that may have left traces in the structures of modern languages?

The findings from paleontological and physiological research tell us that the spectrum of speech sounds that Neanderthals were able to articulate is much more limited than the minimum range of distinct sounds that are known from some of the languages of the world. Neanderthals could perhaps utter ten speech sounds, two vowels, and eight consonants. In addition, they were capable of producing a glottal stop, a sound found in German, Danish, and Finnish. The only modern language of the world with only two vowels (a, e) is Ubykh, an indigenous language of the Caucasus, affiliated with the northwestern group. Consonants in Ubykh, however, number 82, which is among the highest number of consonants in any language. In modern languages such as Hawaiian and Tahitian, the number of consonants is relatively limited, comprised of only eight sounds. As a compensation for this limited range, the full spectrum of basic vowels (a, e, i, o, u) produces a variety of syllabic structures in combination with the available consonants.

Whether or not *Homo erectus*, who lived between circa 1.6 million and 0.4 million years ago, was in the possession of language is still a matter of debate. The ability of this hominid species to produce linguistic sounds was certainly more limited than that of Neanderthals. *Homo erectus* probably relied on visual signals and gestures. Language-related communication would have been limited to sounds expressing surprise, shock, joy, pain, and the like. Such utterances in the form of interjections (such as wow, oh, and yay) are still utilized in the languages of modern humans.

In the 1970s, specialists in language evolution studying Pidgin and Creole languages began to theorize about how these variants are formed. The general impression concerning their formation is that the sound patterns and the grammatical

structures of a sophisticated language become simplified when learned without the control of school education or when used by people with different mother tongues. For example, in Haitian Creole, the sounds and the grammatical techniques of European French are simplified. Tok Pisin, spoken in Papua New Guinea, is based on an abbreviated version of British English.

In a reversed order of development, Neanderthal protolanguage, which predated the development of modern human language, has been compared to the simplified variants of Pidgin and Creole. Such comparisons, however, have not been satisfactory because even the simplest Pidgin languages are more complex than what can be postulated for the Neanderthal.

An intermediate stage of linguistic evolution has been postulated between the primitive Neanderthal protolanguage and the complex linguistic development of early humans. The evidence for this hypothetical stage is highly circumstantial, although some existing languages contain elements that might be remnants of an archaic stage of complex evolution. Some Paleosian languages such as Chukchee, Koryak, and Negidal, for example, lack a clear distinction between word classes (nouns, adjectives, verbs, pronouns, etc.). Also, the object-initial word order used in some peripheral languages of Southeast Asia and Central America—spoken in traditional hunter-gatherer societies—gives the impression of being much older than the

subject-initial word order prominent in most modern languages.

The Aboriginal languages of Australia, which represent the final stage of complex linguistic development, come from a region of the world that was inhabited more than 60,000 years ago. Therefore, if an intermediate stage of archaic complex language existed, it must be older than about 70,000 years. Perhaps the inhabitants of the Blombos Cave in South Africa, who lived some 75,000 years ago, represent speakers of the more archaic transitional stage of complex linguistic development.

■ Introduction: The Origins and Evolution of Art

Among the many definitions of art offered by the online version of the *Oxford English Dictionary*, the following is the most pertinent to the study of the human past: "The expression or application of creative skill and imagination, typically in a visual form such as painting, drawing, or sculpture, producing works to be appreciated primarily for their beauty or emotional power. Also: such works themselves considered collectively." The keys to this defini-

tion, and what makes it so pertinent to the evolution of our species, are the terms "beauty" and "emotional power." Just when did our ancestors begin to create objects that had aesthetic qualities, uses that went beyond simply the utilitarian?

The challenge for the archaeologist and anthropologist is to identify objects that reflect and embody such qualities. But what might those qualities have been for species that were not yet human? And could we as humans recognize

them? This question, of course, suggests that only humans, with our ability to use symbolic expression as a means of communicating thoughts and ideas about the world, could recognize art. Indeed, while we know that many species have advanced cognitive capacities, such as chimpanzees, dolphins, and whales, we do not believe that they have quite the same kind of ability to create symbolic expressions as our own species. Insofar as we know, none of these species have ever created anything that we humans would call art.

Although art may seem to be uniquely human, could any of our ancestors have had the cognitive ability to create objects that we would consider artistic? Although some have argued that *Homo erectus* may have possessed some cognitive skills that would have fostered the creations of objects with an aesthetic sense, most archaeologists now believe that *Homo neanderthalensis* (Neanderthals) did create art, most likely in the form of body decoration and modification. But it is only after the appearance of our own species, *Homo sapiens*, that art really becomes more apparent in the archaeological record. The Upper Paleolithic peoples of Europe certainly created objects with a fine artistic sense, but increasing evidence from Africa suggests that peoples of our species could be said to have created art somewhat earlier, perhaps by 100,000 years ago.

Objects that have an aesthetic dimension are far more numerous as societies begin to settle and become reliant upon domesticated plants and animals. Art in these contexts begins to take on more recognizable roles: decorations in homes, wall paintings, and clay figurines that may have had a role to play in religious practice. After 10,000 BCE, art becomes more familiar to us as the creation of objects that may not have a clearly utilitarian role but have been produced to satisfy some larger purpose.

Why Is There So Little Very Ancient Art?

Although we may say that we know art when we see it, the fact is that art is difficult to define, and because definitions of it are so highly subjective, there is often little agreement even among specialists as to what art is. This problem is even more difficult when one looks back into the very distant past and at the species that are part of our evolutionary lineage. In the very deep prehistory of our evolution, species such as the australopithecines and even early *Homo* had far smaller cognitive capacities and very limited ability for symbolic communication. This suggests that art as we understand it did not exist in this deep prehistory.

If, however, we expand our concept of art to include not simply objects but also attributes of them, we get a sense that art by this definition may have appeared far earlier than expected. Some archaeologists have suggested that Achuelan hand axes are a very early form of art because many of them exhibited a refined sense of symmetry. This is especially the case of those made after 600,000 years ago. *Homo erectus* was the species that created these tools.

More conventional conceptions of early art focus primarily upon those objects that appear to have no obvious utilitarian function. These may include items of personal decoration, such as beads, but also materials that could have been used to paint or otherwise modify the body, such as mineral pigments like ochre of various colors. These pigments may also have been used to color animal bones as well, but whether this was art or something else remains unknown. Ochre and possible pigments have been found at sites in Europe as well as in Africa at Acheulean-era sites. Beads appear far later in human prehistory and only become common after 100,000 years ago as anatomically modern *Homo sapiens* makes its appearance. Some archaeologists also consider artifacts that have deliberate markings, cuts, or gouges on them to be an expression of art. An example of such an object is an elephant leg bone from the Bilzingsleben site (dated to approximately 250,000 years ago) in what is now modern Germany that is inscribed

► THE BEREKHAT RAM FIGURINE

A small piece of lava no more than 1.3 inches (3.5 centimeters) in length excavated from the Berekhat Ram site in modern Israel and dated to 400,000 years ago is considered by some archaeologists to be the earliest known artistic representation yet discovered. This assessment, however, is not without controversy.

The pebble has three grooves scored into it; the grooves have been verified to have been made with a stone tool. The form of the pebble is vaguely reminiscent of a female form with exaggerated hips. Some scholars have suggested that this pebble may be a very early example of the so-called Venus figurines that appear far later in the Upper Paleolithic; however, this speculation is not widely accepted.

If this object is truly a figurine, this means that one form of symbolic capacity appeared far earlier in the evolution of our species than is commonly accepted. Until similar objects are discovered at sites of a comparable antiquity, the interpretation of the Berekhat Ram figurine remains uncertain.

with parallel cuts of similar length. Whether this is art, however, is debatable.

It is only after 50,000 years ago that artifacts commonly recognized as art begin to be found in greater numbers. Not surprisingly, this explosion of art objects, such as carvings of humans and animals in bone and antler, cave paintings, and utilitarian objects with decorative motifs and flourishes, is coincident with the migration of humans—*Homo sapiens*—into South, East, and southeastern Asia; the Near East; and eventually Europe and central Asia. Clearly, our species had evolved a complex symbolic capacity that used objects in new and powerful ways to represent other concepts and symbols.

It is important to remember, however, that the archaeological record is very much biased toward the preservation of durable objects: those made of stone, bone, antler, shell, and sometimes wood. Fiber and body modification, like tattooing or painting, simply does not preserve in such a way that it can be discovered. Thus, art may well have something of a deeper prehistory than is currently conceived, but it is highly unlikely that evidence of this will ever be discovered. It is also possible that cuts, grooves, and other markings on bone may be due to natural processes, and unless such causes can be definitely rejected, it is safe to be initially skeptical of claims of objects that are said to be representative of early art.

A Cognitive Revolution? Competing Theories about Art and Its Meaning

The problem of the origins of prehistoric art and the search for an explanation of its remains are among the most acute issues of scientific and public discussions since the first discoveries of cave art were made in the late nineteenth century. Dozens of theories from multiple perspectives have been offered to explain why it emerged when it did and what it might have meant to the people who created it.

In spite of the obvious differences of methodological and theoretical approaches to the study of prehistoric art, for most scholars and contemporary researchers there is no doubt that it is important to consider the biological and cognitive capabilities of our prehistoric ancestors to fully understand prehistoric artistic creative activity. Such ideas became the starting

point of the so-called biological theory of art origin, proponents of which sometimes describe the origin of art as a cognitive revolution that is viewed as one of the most important phenomena in human history.

Nevertheless, archaeological and anthropological data show that while biological and cognitive premises of creative artistic activity are important, having sufficiently developed minds and bodies does not necessarily lead to the creation of art. Therefore, other theories and hypotheses for the origins of art, primarily those of a cultural or social type, have been proposed.

Magic (or a ritual explanation) of cave art traditionally is regarded as one of the earliest concepts of art and can be traced back to the ideas of Edward B. Taylor. In archaeology, it is usually connected with the studies by Henri Breuil and Henri Begouen at the beginning of the twentieth century. They argued that animals were the center of ritual activity (totemic, magic, and other forms) of Paleolithic hunter-gatherers. Thus, animal images on cave walls most probably were identified with living animals. Inherent to magic is the principle of analogy, which implies that one can control the object if one controls its image. The magic function of cave art is connected with sympathetic magic, hunting, protection, breeding and reproducing, healing, and other rituals and collective ceremonies, some of which, as Jean Clottes has argued, were of a shamanic nature. Such understanding of prehistoric art dominated archaeological thinking until the mid-1960s.

Another approach to the interpretation of art is one that emphasizes its symbolic meaning within a larger religious or mythological framework. Its proponents argued that instead of looking at individual images, it was necessary to interpret them as an integral system of signs, tokens, and symbols, every component of which—location, disposition, co-occurrence frequency, and other parameters—are based upon rules that, in their turn, are caused by general cultural peculiarities of their creators. Supporters of this perspective argue that all images could be and must be deciphered (decoded); this process results in reconstruction of general ideas of a prehistoric population about the universe, life-death dualism, and the basics of human life. Nowadays, similar ideas are developed in frames of

postmodernist and poststructuralist directions of historical and anthropological thought.

The social interpretation of cave art suggests that symbols of any kind could be used to reinforce collective identity (kin, community, ethnic, ritual, etc.). The latest trend in the development of such an understanding of social function of prehistoric art is connected with Late Paleolithic exchange and social networks studies by Clive Gamble and his colleagues.

Communicative and memorial (or mythological) explanations are similar to theories of art that see it having magical or social functions but stress that symbols and images of any art object could reflect collective unity and integrity only if they suggest connection with preceding generations, or early ancestors. They also have a connection to emerging cognitive theories of art.

Cognitive explanations of cave art concentrate on information flow throughout generations, which could be transmitted by images. Interpreting art in general as the peculiar form of world knowledge and information storage, it underscores that only important hunting species were the subject of cave pictures, and prehistoric painters were well informed about animal anatomy and hunting practices. Such information could be used for the preparation of adolescent members of the community for the initiations. Contemporary postmodernists also imply cognitive significance of prehistoric cave art images, regarding them as texts that could be deciphered or images that could be read in order to comprehend past cultures.

The concept of the explosion of information that many scholars believe occurred at the middle of the Paleolithic has become the starting point for ecological-demographic explanation of cave art origins. Climate deterioration created by the last glaciation caused resource shortage, which in turn forced people to move to more suitable places for their subsistence needs. Their concentration in a few niches demanded strict defense and marking of their foraging territories, and art has been proposed as one way this was accomplished. The theoretical background and empirical verification of this hypothesis has been provided by Steven Mithen in the 1990s.

Aesthetic explanation (“art for art’s sake,” or the “game hypothesis”) traditionally is regarded

as one of the earliest in prehistoric culture studies and was proposed by Edouard Lartet and Edouard Piette in the mid-nineteenth century. Nowadays, its proponents usually emphasize the emotional sphere of prehistoric peoples and its display via art and in the creation of monumental compositions of high aesthetic value. This theory suggests that there is no deep meaning of art in terms of social, ritual, or ideological concepts and that it was just art.

In many recent case studies researchers tend to emphasize the primacy of the symbolic function of cave art and its connection with ritual activity of prehistoric communities. The complex character of such compositions, along with their remoteness from cave entrances and from settlements, which ensured high secrecy of the process, tends to support this hypothesis.

Art Objects and Early Ornamentation—Blombos Cave

Modern humans (*Homo sapiens sapiens*) are the last hominid species to appear. According to the findings of human genetics, the origins lie in southern Africa and date back some 120,000 to 150,000 years. Until recently, the artifacts found in the caves from the Upper Paleolithic, dating to no earlier than circa 30,000 years ago in western Europe, were thought to be the oldest evidence for the artistic sense in our species, reaching beyond the practical intelligence to produce tools. This picture has changed with recent finds in South Africa.

Research has been carried out in caves of southern Africa south of the Zambezi River, including Klasies River Cave, Boomplaas, Die Kelders Cave I, and others. Those caves were inhabited by humans during the Middle Paleolithic over 70,000 years ago. Evidence for this comes from the assemblages of artifacts in the caves, such as bone tools, backed blades, raw material for stone tools, etc., and yet those finds have remained controversial as to the exact dating of their cultural horizon.

Since 1991, investigations have been going on also in the Blombos Cave near the southernmost tip of South Africa, the southern Cape shore of the Indian Ocean, about 200 miles from Cape Town. There also, a variety of highly specialized tools for hunting and fishing were discovered. The Blombos Cave distinguishes itself from the other sites by some exceptional artifacts that attribute to the knowledge of the early history of art and ornamentation among modern humans.

Several small pieces of ochre (i.e., iron ore stone ochre) were discovered that belong to the same cultural strata as the tools. Thermoluminescence dating gives a time frame between 70,000 and 77,000 BP for these finds. Ochre is known for its ceremonial use in prehistory and in traditional cultures. Ochre was not an ordinary material in or around the Blombos Cave. It came from an area of at least 20 miles (32 kilometers) from the cave.

The presence of ochre in the old cultural layer of the Blombos Cave speaks in favor of early symbolic activity. Circumstantial evidence for this assumption of a nonpractical use of the ochre pieces comes from ornaments engraved on some of the pieces. Their surface was scraped and polished. The space was then carefully laid out for designs of geometrical ornaments (straight lines and alternating rhombic forms), which were intentionally executed. The ornamentation is proof of the working of a sense of abstractness. Moreover, since many of the lines show parallel patterns, these ornamental designs document a sense of symmetry operating in the minds of those who crafted these pieces.

A cluster of intentionally perforated shell beads, altogether 41, was found during the excavations in April 2004. The beads are red-stained and were likely put on a string and worn. The

shells are from a tiny mollusk (*Nassarius kraussianus*) that populated a nearby estuary.

The finds of art objects and ornamentation in the Blombos Cave close the gap between symbolic activity documented for earlier hominid species such as Neanderthals and *Homo erectus* and the cultural horizon of modern humans. Finds of ornamental beads (ostrich-eggshell beads) similar to those in the Blombos Cave and of high age are also known from Loiyangalani in the Serengeti National Park (Tanzania).

Early South African Rock Art

Sites with rock engravings and paintings are scattered over a wide area of southern Africa, including Namibia, South Africa, Malawi, Zimbabwe, and Tanzania. These sites are known for both naturalistic and stylized images as well as simple and complex abstract motifs.

By the nineteenth century, researchers began to realize that the myriad images preserved on rocks were created by the ancestors of the Khoikhoi (Hottentots) and the San (Bushman) tribes who still live in those areas. Since the indigenous people of southern Africa were considered primitive by European standards, their artistic achievements were overlooked for a long period.

By the 1970s, rock art in southern Africa was finally appreciated as a serious subject of scientific—particularly anthropological—inquiry. In the course of investigations during the 1980s, the motifs and scenes depicted in rock images were associated with traditions and customs observed among the living Bushman tribes. Today, it is well known that the images eternalized on the surface of boulders and on the walls of rock shelters express important aspects of the San belief system and were produced by shamans in a state of trance. Experiments have been conducted with San shamans who identified various abstract motifs in the picture panels as representing living beings and objects from the real world.

San rock art from the Drakensberg Mountains in South Africa. (Victorita/Dreamstime)

In the communal life of the Khoikhois and Sans, the trance (or curing) dance plays a key role. In the rupestral imagery, women and men—predominantly in groups—are often depicted as dancing. Pictures of animals, which have a symbolic or metaphoric role in the trance dance, are rendered in the greatest variety of motifs and styles.

A human motif that occurs in a wide area—from Zimbabwe to the southwestern Cape Province—is a female figure in frontal view with splayed legs and raised arms. This type of figure, sometimes referred to as the mythic woman, is found in contexts where the life cycle theme is addressed.

The two basic categories of rock imagery—engravings and paintings—are found in differing surroundings. Paintings were executed on the walls of rock shelters, usually under sandstone cliffs, while engravings were made on isolated rocks, usually of a smaller size. Paintings have also been found in caves. Some of the cave paintings are among the oldest pictures of southern Africa. The oldest pictures of hunting scenes, made by archaic hunter-gatherers, show humans without bows and arrows. In more recent hunting scenes, men are shown with bows and arrows.

The animal images of the Apollo 11 Cave in Namibia are the earliest that can be dated with some accuracy. The calibrated radiocarbon dates range between 30,000 and 35,000 years ago. It has been speculated that some of the imagery in

Tanzania may be even older. However, no reliable dates are yet available. In some areas, rock art was created for many millennia. For instance, at some sites in the Kimberley region of South Africa, engravings were produced from approximately 10,000 years ago to about the middle of the nineteenth century.

The Rupestral Art of the European Upper Paleolithic

In earlier times, there was much speculation among scholars about the unfolding of human beings' abilities to create images. The origins of iconography or representational art are linked to the advent of modern humans in Europe (around 45,000 BP). Representational art is an innovation that fits in the overall picture of the revolutionary transition from the Middle to the Upper Paleolithic eras. According to the present state of knowledge, the earliest evidence for image making is not older than approximately 35,000 years ago, and this comes from Europe. The combined manifestation of image making and symbol making as full-fledged capacities, documented for the horizon of modern humans, marks a leap in the evolution of culture when compared with earlier hominid species that were capable of symbol making but lacked representational art.

There are two regions in Europe that harbor representational art of the Paleolithic Age. These both lie on the peripheries, one in western Europe and one in eastern Europe. Well known are the painted caves in southwestern France and northern Spain where the earliest images were discovered. Rupestral art (also called parietal art) from the Paleolithic era is also known from Russia. The pictures in the caves of the southern

Ural Mountains (Kapova Cave, Ignatievka Cave, Serpievka Cave) are not as abundant as the imagery in western Europe, but they are also masterly executed. The best explored of the Paleolithic caves in the Ural Mountains is the Ignatievka Cave.

The western tradition of Paleolithic art flourished throughout the latter period of glaciation while, in the east, rupestral art of the caves emerged toward the end of the last Ice Age. For this reason, the imagery in the Ural caves is younger than most of the pictorial traditions in western Europe and dates to the latest phase of Paleolithic cave art. The presence of humans in the Ignatievka Cave is contemporaneous with the youngest painted caves in the west. The period when Paleolithic art was produced is sometimes called the Age of the Reindeer because this animal, together with the mammoth, was the most preferred for hunting and accounted for most of the meat diet of the archaic hunters.

Most of the painted caves in France and Spain were discovered in the late nineteenth century and in the first half of the twentieth century. Besides Altamira in northern Spain, the most widely known sites with Paleolithic art are Lascaux (department of Dordogne in southwestern France), Les Trois Frères (Ariège), Pech Merle (Dordogne), and several others.

Some spectacular discoveries were made in the 1990s. The Cosquer Cave (Bouches-du-Rhône) near Marseille, with its underwater entrance, was discovered in 1991, and the Chauvet Cave (Ardèche) was discovered in 1994. The paintings and engravings of the Chauvet Cave are the oldest so far known, dating back to circa 32,000 BP. The oldest radiocarbon date for the Cosquer Cave is circa 27,000 BP. Paleolithic rupestral art was produced for about 20,000 years. The youngest of the painted caves, Le Portel (Ariège), dates to circa 11,600 BP.

The space in the caves is subdivided into many chambers, corridors, and tunnels. Paintings were not executed indiscriminately in all parts but instead concentrate in certain areas, in particular chambers, at prominent gateways, at places with exceptional rock formations, and the like. In most caves, no paintings are found

➤ CAVE OF LASCAUX (FRANCE)

The Cave of Lascaux is situated in an area of the département Dordogne in southwestern France where several other painted caves have been discovered. The cave had been sealed off by debris for many millennia. In the 1920s, one of the pine trees that had grown in the area fell down, and under its roots a crack opened in the soil with an opening like a foxhole at the bottom. Farmers kept the hole blocked to prevent cattle from falling in. In September 1940, a group of youngsters decided to explore the hole and find out what lay beneath it. What they found was to become a world sensation.

Hundreds of images of animals and numerous geometric signs are scattered over the walls and ceilings in different sections of the cave, which stretches over a total length of 820 feet (250 meters). The most richly decorated is the Rotunda or Hall of the Bulls, which has been described by Ruspoli as containing “the most majestic pictorial composition and the largest figures known from prehistoric times.” Also in the Passageway, the Nave, the Chamber of the Felines, and in other sections, there are painted and engraved pictures. The images were produced during the Early and Middle Magdalenian period, and the cave was occupied about the time of maximum glaciation (between ca. 21,000 and 17,000 BP).

The animal species that are depicted in the Cave of Lascaux also appear in the imagery of other caves. There is, however, an element in the imagery that is typical and exclusive of Lascaux, and these are the so-called disjointed signs, a category of the geometric signs. These composite signs whose constituents are disjointed have been interpreted as ethnic markers by which Lascaux, as a cultural province, distinguished itself from other regions.

In addition to the images and manifestations of the creative human mind, many remainders of the materials and tools used by the artists have been found in the cave, among them various pigments for producing different shades of colors. There are some special finds by which Lascaux distinguishes

itself from other Paleolithic caves. At Lascaux, more than 100 stone lamps have been found, and in the Chamber of the Felines the imprint of a rope was preserved in hardened clay. This is seen as evidence for some kind of scaffolding that was used in the cave for the artists to reach otherwise inaccessible parts of the vault.

The cultural space of the Cave of Lascaux has been frequented by millions of visitors. Already several decades ago, it was noticed that the exhalation and perspiration of masses of humans in the vault causes algae to cover the surface of the walls and the paintings. A replica of parts of the original cave (i.e., the Rotunda and the subsequent Axial Gallery) was reproduced in a concrete blockhouse in a quarry not far from the original cave. The replica (Lascaux II) was opened to the public in 1984.

➤ ALTAMIRA (SPAIN)

The Cave of Altamira, in the province of Santander (northern Spain), was first visited in 1875. At that time, the Spanish discoverer Don Marcelino Sanz de Sautuola did not notice the paintings in the deeper chambers of the cave. In 1879 after having been inspired by the pieces of mobile art that had been on display at the 1878 Paris Universal Exhibition, Sanz de Sautuola started to explore the Cave of Altamira in search of pieces of art of those people who had frequented the place in earlier times. The story goes that the explorer kept his eyes fixed to the ground while his daughter Maria looked up. It was she who discovered the paintings in what was to be called the polychrome chamber some 100 feet (30 meters) from the entrance.

In a booklet that Sanz de Sautuola published in 1880, he describes some artifacts, decorated bones, and other remainders such as pigments that he had found near the entrance. He introduced the cave paintings and identified one of the animal species, the bison. This kind of art from the times of the Ice Age had been totally unknown until then. The public reacted negatively since, in the minds of the contemporaries, no categories existed to evaluate the early rupestral art in its proper cultural context. Sanz de Sautuola even had to face accusations of being a forger, and the wall paintings in the cave were dismissed as a hoax. On the occasion of the Congress of Prehistoric Archaeology, held in Lisbon in 1880, a visit to the Cave of Altamira was arranged, but none of the delegates showed any interest in the manifestations of the so-called savage mind of prehistoric people. It was not until the early twentieth century that the authenticity of the cave paintings at Altamira was finally acknowledged.

The Cave of Altamira is about 1,000 feet (300 meters) deep and is divided into numerous cham-

View of the 14,000-year-old painted bison on the ceiling of the Polychrome Chamber in the Altamira Cave in northern Spain. (AP Photo/Pedro A. Saura)

bers and gateways. Paintings and also some engravings are found in many sections, although they concentrate in the Polychrome Chamber. On the ceiling in the chamber is the Great Panel with more than 30 large images, mostly of bison. The animals are depicted in black and in red with shades of red dominating. In the Great Panel, there are also claviform (club-shaped) signs and some other geometric motifs.

The cave was frequented by humans for several millennia. Paintings were executed between circa 16,500 and 14,500 BP. Occupation of the cave ended when the entrance was closed by collapsing rocks at a length of 20 feet (6 meters) around 13,000 BP.

Bibliography

Beltrán, Antonio. *The Cave of Altamira*. New York: Abrams, 1999.

near the entrance with the exception of the Cave of La Pasiega (Santander, Spain), whose imagery abounds with abstract symbols.

Although neither the public citizens nor scientists in the nineteenth century took much interest in the primitive art of prehistory, the mastery of those early manifestations of the human creative mind was celebrated in later periods. Pablo Picasso is frequently quoted as having said, following a visit, “After Altamira, all is decadence.”

The paintings in the caves of southwestern France and northern Spain show a great variety of images, both in form of isolated pictures and in groupings. The style of many images is naturalistic, while others show a high degree of stylization. There are different styles that change over time. In the 1960s and 1970s André Leroi-Gourhan elaborated a typology of style for Paleolithic art that has gained wide appreciation. The following types are distinguished:

Style 1: Aurignacian, some 30,000 BP; crude contours of animals; symbols of vulvas

Style 2: Gravettian and Early Solutrean, ca. 25,000–20,000 BP; animal figures with a prominent cervico-dorsal line; female figures in bas-relief

Style 3: Later Solutrean and Early Magdalenian, ca. 20,000–15,000 BP; a higher degree of stylization; experimenting with different proportions; abundance of abstract motifs

Style 4: Middle and Upper Magdalenian, ca. 15,000–10,000 BP; images in an elaborate realism, with a richness in details; great variety of abstract motifs

The images in most of the Paleolithic caves in France and Spain belong to the period of Style 4.

In many cases of depicted animals only the contours are given, emphasizing basic features.

Other images are more elaborate and show more detail. There are panels that are comprised of naturalistic pictures of mostly animals and, in some assemblages, also of human beings. The species that are represented in the cave paintings all belong to the bestiaries of the hunter-gatherers who lived in the areas of the caves. Among the animals are felines, mammoth, bison, aurochs, rhinoceros, bear, horse, deer, ibex, goat, and others.

The animals are not depicted in their natural environment. In the scenes in the caves, there are no clues as to the habitats of the animals, no riverine meadows for grazing, no plains to be roamed by the beasts. The pictures do not show the true proportions of the animals. A mammoth may be smaller in size than a horse or a deer. Some of the animals are depicted as standing upright or in other positions that are unnatural,

➤ CHAUVET CAVE (FRANCE)

The Chauvet Cave is one of several caves in the river valley of the Ardèche west of the Rhône in southern France. In the early 1990s, three people systematically explored the sites in the gorges of the Ardèche, and on December 18, 1994, they found the cave that was later named for the leader of the expedition. After the dating of some pigments in the contours of the paintings, the age of the images was revealed. These are the world's oldest known paintings. The series of radiocarbon dates for Chauvet range from 32,400 to 30,300 BP.

The accessible parts of the cave are some 1,700 feet (500 meters) long. The ceilings are relatively high—between 50 feet (15 meters) and 100 feet (30 meters)—as compared to the heights of vaults in other caves. For instance, the ceilings at Lascaux are between 10 feet (3 meters) and 20 feet (6 meters) high. Major sections of the cave are the Hall of the Bears, the Panel of the Horses, the Lion Panel, the Panel of Hand Prints, the Panel of Hand Stencils, the Candle Gallery (with concretions in red and orange), and the Cactus Gallery (with lines drawn in red ochre). One of the artistic techniques that seems to be exclusive for the Chauvet Cave is the crafting of the image of an animal with the help of red dots (as filling and for marking contours) as in the Panel of Red Dots.

➤ IGNATIEVKA CAVE (RUSSIA)

The Ignatievka Cave, with its portal situated about 36 feet (12 meters) high from the bottom of the valley in the slope of the sandstone canyon of the river Sim, has been mentioned in the sources since the nineteenth century. Russian archaeologists first visited the cave in 1968. The paintings in the deep cave were discovered as late as 1980. With its length of 1,875 feet (626 meters), the cave is a true labyrinth. It was occupied by humans between circa 14,200 and 10,400 BP. Most of the pictures were executed between circa 14,000 and 13,000 BP.

The greatest concentration of images is found in the deepest chamber of the cave, the end hall. There, pictures are grouped in two panels, a red panel and a black panel. The images in the red panel are the largest of the cave. The scene depicted in the red panel seems unreal and is obviously imbued with mythological meaning. On one end, there is the large image of a woman (more than 3 feet, or 1 meter, tall), with breasts hanging down on both sides and with parted legs as in a birth-giving position. The vulva is marked by a concentration of red ochre. Rows of dots (altogether 21 in number) are placed between the

legs, with 12 dots in the longest row originating directly from the vulva and others in rows of four and five dots. The long row of dots points to another row of 21 dots on the other side of the scene. That row is associated with the breast of an animal, most probably a wild bull.

The elements of this scene have been associated with motifs and narratives of Eurasian mythology, with Uralian traditions in particular. The female figure may be identified as the divine Ancestral Mother (the Ural Mother), the Creatrix of all living things, the Mistress of Nature. The meticulous elaboration of the rows of dots recalls Uralian mythical numerology (with 4 symbolizing the male principle, 5 symbolizing the female principle, and 7 serving as the sacred number and 21, or 3×7 , as its potency). Perhaps one finds the roots of mythopoetic concepts about the world among Uralian and Siberian peoples reflected in the imagery of the Ignatievka Cave. It is assumed that the end hall was a sanctuary frequented by humans for performing rituals (e.g., for celebrating rites of passage).

—Harald Haarmann

such as a horse standing back to back with a reindeer as in the Cave of Las Monedas (Puente Viesgo, Spain). The animals were painted at remote places in the depth of caves that they never inhabited. This is true also for the cave bear that did not camp at a distance of many hundreds of feet from the entrance.

Most probably, the representation of animals in the form of usually painted and more rarely engraved images had a symbolic significance. The animals were mythical beings whose spirits were captured in the images. The Paleolithic rupestal art was not intended for decorative or ornamental purposes. Painted walls and ceilings are found in the depths of the caves, in dark places where humans never lived and that were visited only to perform rituals and hold ceremonies (e.g., rites of passage to commemorate stages in the life cycle). In some caves, there were pedestals that suggest ceremonial places, such as in the Chauvet Cave that has a bear skull positioned on top of it and the bones of bears strewn around it.

Images of human beings are of much rarer occurrence than those of animals. In some settings, humans are depicted as hybrids (half human, half animal) or are dressed in a bear's fur (such as the figure of a sorcerer in the Cave of Les Trois Frères). In modern interpretations, hybrid creatures or humans in strange attires are identified as shamans who, in ecstatic trance, seem to shift their identities and merge with the spirits of animals. On the walls of the painted caves are many depictions of isolated parts of the human body, in particular hands (i.e., hand stencils) and vulvas. These motifs obviously had a symbolic meaning for those who painted them. The motif of the vulva is of frequent occurrence in Paleolithic symbolism and can readily be associated with the female principle of the life cycle of nature (birth, growth, death, and regeneration).

Alongside naturalistic images and motifs with symbolic meaning there is a variety of abstract motifs (zigzag signs, undulated lines, grid signs, dots, strokes, lozenges, etc.). In many caves, ab-

stract motifs may appear in isolation, and certain individualized forms may appear in groupings without any association with other motifs. There are painted walls of caves with abstract motifs only, as in the El Castillo Cave (Santander). Here, the dot is the basic motif and features on the wall in rows of three (extending to the left and right) and in four (in a vertical alignment).

The abstract signs are evidence for symbol making as an elementary capacity of Paleolithic people. The origins of this capacity go back in human evolution as far as *Homo erectus* (ca. 1.9 million–400,000 years ago). In the beginning of research on rock art, the existence of abstract motifs in the picture friezes of the Paleolithic caves was hardly taken notice of, and the repertoire of abstract signs was marginalized. Modern analyses of Paleolithic rock art pay due attention to both pictures and abstract motifs.

The panels where abstract motifs appear are as old as the friezes with pictures in natural style. Consequently, humans have demonstrated the dual capacity to produce naturalistic pictures and abstract signs from the time of their earliest cultural activities onward. The synchronic manifestation of the dual visual capacity provides evidence that the sense of abstractness is not a secondary achievement in the cultural evolution of humans but instead is as primary as the sense for naturalism.

In the Upper Paleolithic era, the synchronicity of naturalistic representation and the presence of highly abstract motifs in the pictorial record highlight the independent functioning of two elementary capacities (image making and symbol making) in modern humans. Where pictures of animals appear in close association with abstract motifs (e.g., the image of an aurochs in the La Tête du Lion Cave, Ardèche, with a set of dots painted above the back line of the animal or a horse with superimposed hand stencils in the Cosquer Cave, Bouches-du-Rhône), it becomes clear that the visual elements of both categories (iconic and abstract) form a meaningful unit, although the interpretation of the narrative groupings in question remains, for the most part, speculative.

The pictures, symbols, and abstract motifs are depicted in different colors. These may appear either separated or in multicolored pic-

tures. For example, black (executed by using charcoal or manganese dioxide) is the dominating color in the paintings of the Chauvet Cave, while in the Cave of Altamira, red (executed by ochre or iron oxides) dominates.

The epoch in human cultural history during which the rupestral art of the Upper Paleolithic period flourished came to an end when the fauna of the Ice Age, especially the big hunted animals such as the mammoth, left western Europe under the pressure of global warming, which marked the transition to the postglacial period, and moved toward colder regions (to northeastern Europe and to Siberia). The culture of the big game hunters fell into decline and with it the tradition of cave painting.

The Mobiliary Art of the European Upper Paleolithic Era

The beginnings of representational art are associated with the advent of modern humans (i.e., *Homo sapiens sapiens*) in Eurasia. The earliest manifestations of the human creative spirit for representation date back more than 32,000 years. Representational art appears in two major categories: rupestral art (as in the paintings of the Paleolithic caves) and mobiliary art (also called mobile or portable art). The difference is basically one of the dimensions of representation.

Paintings on the walls and ceilings of caves are two-dimensional, while mobile art is three-dimensional. And yet the distinction between

► THE HOHLENSTEIN-STADEL LION-MAN

The Paleolithic sculpture from Hohlenstein-Stadel in southern Germany is an exceptional piece of mobile art in many respects. In size, it differs from other similar finds because of its great size. The statuette, which has been named lion-man, measures 11.5 inches (29 centimeters) in height, while other figurines are much smaller. The sculpture is made of mammoth ivory. This piece was found in a cultural layer of the Aurignacian period and is dated to circa 32,000 BP.

The figure was found in August 1939 and was broken into more than 200 small pieces. These were retrieved from the Stadel Cave in the valley of the Lone River near the town of Ulm in the federal state of Baden-Württemberg in southern Germany. The material of the figure was stored in a box together with bone fragments. In the late 1960s, a German archaeologist attempted a reconstruction that, however, remained incomplete. In later excavations, additional pieces of the head and an arm were found. In 1987–1988, a restorer from the Württembergisches Landesmuseum (Stuttgart) succeeded in completing the reconstruction, revealing the sensational nature of the sculpture.

The lion-man is a rare specimen of a therianthrope figure, with hybrid anthropomorphic and zoomorphic features. The body is that of a male human standing upright with his arms hanging down, while the head is that of a lion. Such hybrid figures are rare in the archaeological record of the Paleolithic Age. This category of therianthrope pieces becomes more frequent and verified with respect to stylistic and feature-oriented variation during the Neolithic period, particularly in the context of figurine production in southeastern Europe.

—Harald Haarmann and Joan Marler

the dimensions is sometimes blurred. In the paintings of many caves, the artists adjusted to the natural formations of the rock in such a way as to make use of certain dimensional features. For example, the lower part of the body of a depicted deer may be delimited by the edge of a rock panel, or a vulva sign may be carved into a soft deepening in the wall that resembles the female pubic triangle.

In the Paleolithic caves, we find sculpted human figures in bas-relief, such as the image of the Venus of Laussel with elongated breasts and curving hips and holding a horn. In these and other cases, the boundaries between two-dimensional paintings and three-dimensional representations of imagery are floating. There are also cases of three-dimensional sculptures that are fixed to the ground and are thus immobile. This is true, for example, for the clay sculpture of a bear in the Montespan Cave (Haute-Garonne) that is attached to the floor of a ceremonial space.

The early finds of Paleolithic artifacts belonging to the category of mobile art were made in the 1870s. At that time, none of the painted caves had yet been discovered. In 1878, some of those pieces were displayed at the Paris Universal Exhibition and raised the attention of the Spaniard who later explored the Cave of Altamira and whose daughter was the first to notice images of animals there. Before the discovery of the Chauvet Cave in 1994, it was believed that the beginnings of mobile art would reach farther back in time than the origins of rupestral art. The oldest pieces of three-dimensional imagery are some 32,000 years old. This is the age of the oldest paintings in the Chauvet Cave.

Artifacts that fall under the category of mobile art distinguish themselves from ordinary tools because of their nonpractical symbolic functions. The following can be identified as the major types of such pieces: zoomorphic figurines (small size, measuring a little more than an inch); anthropomorphic figurines (predominantly depicting nude females and usually of small size); hybrid sculptures with zoomorphic and anthropomorphic features; decorated bones (batons), antlers, etc.; personal ornaments such as jewelry (i.e. necklaces, bracelets, pendants) composed of perforated beads, teeth, bone plaques, etc.; and accessories (e.g., belts).

In addition, there is a special functional type of mobiliary art with pieces that have a practical function but are crafted and/or decorated as pieces of art: spear throwers (e.g., one in the shape of a leaping horse from Bruniquel/Tarn-et-Garonne) and stone lamps (e.g., one from the Cave La Mouthe/Dordogne with the image of an ibex on the underside).

➤ VENUS FIGURINES AND THEIR MEANINGS

The representation of the female body in art looks back on a tradition of more than 32,000 years. Some female figurines of an early date—executed in mammoth ivory or bone—are known from western Europe and from the settlement of Malta near Lake Baykal in central Siberia. The oldest figurine so far known—some 2.3 inches (7 centimeters) long—is approximately 31,000 years old and was found at Galgenberg (near the town of Krems in Lower Austria) in 1988. This particular figurine was named “Fanny, the dancing Venus of the Galgenberg” (after an Austrian dancer, Fanny Elssler, of the nineteenth century) and depicts a woman in an obvious dancing posture with her left arm raised.

Many of the figurines from the Upper Paleolithic period were found during excavations and explorations of Stone Age sites in the late nineteenth century and the early twentieth century. Those who found such figurines were caught in the aesthetic zeitgeist. Nakedness was the first property of the figurines that strikes the eye. According to the moral standards of contemporary society in western Europe, nakedness was tolerated only in one public sector, the arts. In that domain, the Greek goddess Aphrodite and her counterpart Venus in Roman civilization were the preferred objects of painters and sculptors. In a generalizing and stereotyping view, the naked female figurines of the Stone Age were associated with the goddess of love of antiquity and labeled as Venus statuettes. The artifacts are catalogued under those labels (e.g., the “Venus of Willendorf” in Austria, the “Venus of Lespugue” in France) in the museums up to the present.

The association with Venus is misleading also from an aesthetic standpoint. Many figurines depict mature women with protruding breasts, belly, and buttocks rather than young women. The idea of the Mother Goddess is a more natural visual association with such figurines, and the identification of religious cults for the Stone Age on the basis of ideas relating to fertility and motherhood remained popular for a long time. In more modern interpretations, the Paleolithic female

Venus of Willendorf, limestone, about 28,000–25,000 BCE. (Jupiterimages)

figurines have been identified, in metaphoric terms, as the embodiment of ancestor spirits (e.g., in the role of the ancestral mother) or as various categories of epiphanies of a goddess (e.g., as the Giver of Life and Death, as the Mistress of the Life Cycle, as the Ancestral Mother, as the Nurturing Mother, as a Guardian Spirit of the Hearth).

It is clear from the occurrence and frequency of female figurines amid the Paleolithic imagery that these artifacts carried symbolic meaning and played a significant role as cultural markers in the communities of people whose worldview was spirited.

—Harald Haarmann and Joan Marler

Although many early artifacts of mobile art have been found at Paleolithic sites in Europe, there are also finds in other parts of the world that are just as old. For instance, the oldest sculpture of a bear was found in central Siberia at Tolbaga near Lake Baykal. The age of that piece is about 35,000 years. In the European context, finds of Paleolithic mobile art are more numerous than in Siberia, and the chronology of their production stretches over a longer span of time, more than 20 thousand years (from ca. 31,000 to 9,000 BP).

The sites with finds of mobiliary art from the Paleolithic Age are scattered over the southern part of the continent, from Spain and France to Ukraine and Russia. The oldest pieces come from sites in southern Germany and Russia, the youngest in France and Russia (southern Urals). Many pieces of mobile art were found in the dwellings of the Paleolithic people. These peoples preferred to live in open rock shelters. Those shelters are scattered throughout central and southern Europe in areas that lay south of the great ice cap that covered the northern part of the continent during the time of glaciation.

Mobiliary art is also known from the caves with painted imagery although not from the deep chambers. The pieces from the caves form part of the ensembles of symbols, imagery, and artifacts with functions in the context of ceremonies and rituals. Within people's living spaces, the pieces of mobile art were kept in places that were separated from tools and artifacts for daily use.

The pieces of mobile art differ in size, proportions, and style. Some of the oldest pieces are very small, such as the animal figurines from Vogelherd and Stratzing in southern Germany and the human figure with raised arms in bas-relief on an ivory plaque from Geissenklösterle. They measure not more than 2 inches (5 centimeters). Perforated artifacts that were used as pendants (fox canines, ivory items) are also small in size. Larger pieces such as the statuette of the lion-man from Hohlenstein-Stadel are rare.

As in rupestral art, in Paleolithic mobiliary art one can distinguish between imagery that depicts animals and other pieces that represent human beings. The selection of animal species that are sculpted is more limited than the great vari-

ety of species that are depicted in the caves. Nevertheless, the major species such as feline, bison, mammoth, bear, and horse are represented. Things are different with respect to human figures. There is an abundance of female statuettes and only a limited number of male sculptures, including hybrids such as the lion-man. Such proportions in the mobile art do not find their parallels in the canon of depicted human beings in the rupestral art. Here, the prominence of female imagery is marked by the abundance of vulva motifs and their frequent occurrence.

The batons (also called command sticks) represent a category of artifacts that illustrate how permeable the boundaries are between the realm of decorative function and symbolic meaning. The batons are long bones or antlers that are decorated with images and sometimes incised with symbols. The intentional alignment of incisions on these sticks has been identified as a form of notational system recording calendrical information (e.g., about moon phases).

The command sticks received their name because they have been interpreted by some scholars as status symbols of political power. However, the existence of complex leadership in the communities of Paleolithic hunter-gatherers is unlikely. It seems more plausible to associate the command sticks—together with the other pieces of mobile art that had a function outside of daily affairs—to the belief system of those people for whom the world was spirit-filled. The command sticks may well have served as mnemonic devices and/or requisites for shamans to perform communal ceremonies, healing sessions, or rituals of divination.

The most sensational finds of Paleolithic jewelry come from burials near Sungir (Russia), some 95 miles (150 kilometers) east of Moscow. The date for this early burial site is given as circa 32,000 BP. The grave goods in two of the burials that were originally dug into the permafrost were exceptionally rich. One was the grave of a boy, the other that of a girl. In the boy's grave a belt was found with 250 canine teeth of the polar fox and with some 4,900 beads. The jewelry of the girl included, among other objects, a total of 5,274 beads. The wealth of the grave goods has been interpreted by some as indicating high social status of the deceased. Other scholars reject

the assumption of a stratified society in the Paleolithic and see those who were buried as members of a prominent lineage, and thus the grave goods would not honor individuals but instead would signal collective reverence for a group of ancestors.

Decorative and Ornamental Art from the Near East and Anatolia

The basic concept of art and ideas about decorative and ornamental art derive from classical Roman antiquity. The meaning that Westerners attribute to these terms is imbued with the spirit of antique European civilization. Within this conceptual frame, "art" stands in opposition to nonart (e.g., tools, utensils, objects for practical use), while what is decorative and ornamental is contrasted with the visualization of religious ideas and with symbols intended to convey information.

The categorizations mentioned here cannot be applied, without reservation, to the realities of visual expression in prehistory, since the conceptualizations of both visible and of invisible culture (i.e., the relationships between the symbolic meanings of artifacts) were not as rigidly divided as we know it from our Western tradition. Much of what a modern observer would call decoration or ornamentation may well have

carried symbolic or metaphorical meaning for the bearers of prehistoric cultures. In most cases, the symbolic connotations of prehistoric art were lost after the decline of the cultures of origin, and they can only be reconstructed tentatively and fragmentarily.

Unlike Europe with its abundance of art produced during the Upper Paleolithic, the documentation for the Near East for the Late Paleolithic is scanty. The beginnings of decorative and ornamental art go back to the transitional phase from Paleolithic hunter-gatherers to sedentism (twelfth and eleventh millennia BCE). The earliest pieces belong to the cultural horizon of the Natufian. These are decorated bone artifacts with carvings depicting animals.

The earliest manifestations of naturalistic representation from sites of the early cultivators-hunters are animal figures executed in bas-relief technique on stone pillars from Nevalı Çori and Göbekli Tepe (in modern Turkey). As for their cultural chronology, those early pictures of animals belong to the prepottery age (tenth millennium BCE). The earliest statuary at the mentioned sites is contemporaneous with the ornamental reliefs.

According to our current knowledge, there seems to be a hiatus of more than 1,000 years in the tradition of ornamental art between the ninth and seventh millennia BCE, when it "reappears" again in different genres. The fullest documentation of the contemporary artistic production comes from Ain Ghazal (Jordan), where in addition to clay statues and animal figurines, motifs painted on walls and floors were found. The context of artifacts and motifs in their specific assemblages has led scholars to the conclusion that all these manifestations of "art" were related to mythical ideas in a spirited world and make the impression of what Schmandt-Besserat termed "an explosion of symbolism."

The tradition of decoration and ornamentation does not show continuity even from the seventh millennium BCE onward. Its preferences and gravitations vary in space and time. For instance, at Ain Ghazal (east of the Jordan River, Jordania), with its wealth of representational art and decoration in the early phase, the custom to decorate graves vanishes from the archaeological record in the first half of the sixth millennium BCE. At Çatalhöyük in Anatolia, wall painting

➤ WALL PAINTINGS AT ÇATALHÖYÜK

The Neolithic town of Çatalhöyük, located in the Konya plain of central Anatolia, was inhabited from circa 7400 to 6000 BCE. This Neolithic settlement is known for its unique architecture of interconnected houses (entered through rooftop openings) and by an abundance of wall paintings in three major colors: red, black, and white. The dominant color is red, ranging from brownish-red to pink and orange-red. Most of the paintings on plastered walls were discovered by British archaeologist James Mellaart in the early 1960s, although new frescos are still being found, often under a cover of white plaster.

The major motifs that appear in the paintings are animals, human beings, and geometrical symbols. These motifs are not isolated but instead are grouped in narrative scenes. Human figures often appear to be engaged in dynamic communal rituals. Some figures are shown naked, while others seem to wear girdles or skirts, perhaps made of leopard skins. This is suggested by skirtlike dresses covered with spots, some with tails hanging down. Deer, wild boar, leopard, and bull predominate in pictures of fauna.

The largest image found so far is that of a red bull, which is about 6 feet (2 meters) long. This bull is painted in the center of a scene surrounded by hunters in dancing postures holding weapons. One human figure is kneeling on the back of the bull. Is this a precursor of the bull-leaping scene in the Minoan palace of Knossos of the second millennium BCE? Some motifs may have metaphorical allusions, such as the images of two cranes, in black color, facing each other in a dancing posture.

Cranes are known for their elaborate mating dances.

Among the exceptional sceneries is an assemblage of rectangular shapes with subdivisions marking the interior spaces that make the impression of a layout of the ancient city. Unique is the scene where two leopards face one another in relief. The design on the animals' skin is rendered, in painting, as rectangular black forms with a white crosslike motif as a filling.

Evidently related to the mythical world of the inhabitants of Çatalhöyük and, presumably, to their burial customs are scenes with big birds (vultures) in close association with headless human figures. These settings might reflect the custom of open-air burials, with the defleshing of the corpses by vultures.

In addition to the abundance of naturalistic images, there are a variety of abstract motifs, some with geometrical shapes (i.e., triangles, rhombic forms, zigzag lines) reoccurring as ornamental friezes. Most probably, some of these motifs did not function simply as elements of decorative design but instead carried symbolic meaning. This idea is supported by the presence of hand stencils in association with abstract motifs.

remained popular during the whole cultural sequence, while in contemporary 'Ain Ghazal, the same art genre always occupied a marginal role for communal life.

Jewelry (i.e., bracelets, necklaces, pendants, beads), as a category of decorative art and as an identifier of cultural continuity throughout the Neolithic and beyond, forms part of the archaeological record in all parts of the Near East and Anatolia. Especially exquisite and varied is the jewelry from Çatalhöyük.

Rupestal Art in the Americas

Petroglyphs are found throughout the Americas as well as in many regions of the world. Engravings on rocks were never intended as mere decoration. Since Paleolithic times, rock art has been used to express images of cultural significance. Many of the motifs are integrated in picture friezes expressing highly symbolic visual narratives.

In the Americas, it is rare to find petroglyphs in caves. Most are found on the walls of rock shelters or on isolated boulders in the open, which distinguishes them from those in Europe. Although rock engravings are known in almost every state in the United States and throughout Canada, they are especially concentrated in the western, northwestern, and southwestern regions of North America and in British Columbia. Petroglyphs are found from northern California to Baja California (Mexico). They also abound in Oaxaca, southern Mexico, and in the Andean region of South America. Most modern discoveries of rupestal art have been made in the eastern part of Brazil. The southernmost images are found in Tierra del Fuego at the tip of South America.

In general, petroglyphs in the Americas have been produced from the end of the Ice Age, some 12,000 BP into the historical era. In some areas, the tradition of rock art is relatively young, as in the Upper Ohio Valley where petroglyphs were produced by Algonquian-speaking tribes between circa 1200 and 1750 CE.

It is noteworthy that the oldest dates attributed to rock art locations are found in South America, not in the Northern Hemisphere, although the Paleo-Indians arrived from the north. The controversial dates for sites such as Goiás in northern Brazil (ca. 43,000 BP) and Pedra Furada in northeastern Brazil (between ca. 30,000 and 25,000 BP) do not fit the conventional time frame for the earliest migrations of humans from Siberia to North America (between 13,000 and 11,000 BP). Taima-Taima in northwestern Venezuela (ca. 13,000 BP) and Monte Verde in central Chile (ca. 12,500 BP) still predate the oldest sites in North America.

The living conditions of the Amerindians are reflected through time in the narrative themes of their rock art. The oldest engravings may have been made by archaic hunters who did not yet

use bows and arrows. Their imagery abounds in isolated pictures of animals. The second stage is that of hunter-gatherers whose diet included fruits and seed plants as well as wild game. The following stage of socioeconomic development was mixed economies with small-scale horticulture supplemented by traditional hunting and gathering. Later developments include agriculture as the major subsistence economy. For the agrarian communities rain was a major issue, and their petroglyphs indicate water rituals and animals associated with rainmaking (especially in the arid U.S. Southwest).

The American tradition of rock art contains naturalistic and stylistic images as well as abstract motifs (single forms such as lines or dots, complex forms such as geometrical symbols, hand stencils, etc.) as found in other areas of the world. Naturalistic images and abstract motifs often appear in the same context, such as human figures, highly stylized supernatural beings, and animals, including reptiles and birds.

The selection of visual motifs concerns culturally specific symbolism related to local belief systems. Therefore, spiritual beings were sometimes depicted more often than were creatures found in the actual environment. In some sites in eastern Brazil, for instance, birds that were not necessarily common in the area and were not used for food are found in abundance in early rock art. Birds did, however, play a major role in local mythologies as embodiments of spirits and human souls.

In some areas, knowledge of the symbolism of the richly condensed pictorial assemblages has been lost over time and can only be tentatively reconstructed. In other instances, the contents of visual narratives can be associated with the oral traditions of the Amerindians whose ancestors composed the picture friezes. One such site is found near Red Lake in Canada, with narratives in well-arranged rows of pictorial symbols. These resemble the pictorial writing of the Walam Olum, the myth of origin of the Ojibwa that was scratched on several sheets of bark of a birch tree. This pictorial technique for recording information by visual means, called *kekinowin* in Ojibwa, can be seen as a later echo on perishable material of more ancient engravings on stone.

■ Introduction: The Nature of Ritual and Religion

Religion is hard to define. Many scholars have lamented that there is no universally applicable definition of it. There is real, not simply theoretical, disagreement, uncertainty, and unease about what religion is and whether it is a universal element of the human experience. Most anthropologists agree that some sort of “spiritual experience” is a cultural universal but that religion “proper” is not to be found in simpler societies. This of course reflects a bias toward definitions of religion that describe highly formal ecclesiastical spiritual practice found within hierarchical societies. But it is the case that religion as a highly systematized body of knowledge and practice is hard to identify in relatively simple and nonhierarchical societies. Although people “have” religion, finding it presents real challenges to the ethnographer, not to mention the archaeologist.

Not fully understanding what religion is does not make impossible understanding what it does. Indeed, by using standard definitions of religion together and to see what they emphasize, it is possible to get a sense of what roles it can play within any society, be it simple or complex. For Edward Tylor, religion was “belief in Spiritual Beings.” He argued that religion was best seen as an attempt by people to understand the world in which they live. For Emile Durkheim, religion was a so-called social fact and served as a “unified system of beliefs and practice relative to sacred things, that is to say, things which are set apart and forbidden—beliefs and practices which unite into one single moral community called a church, all of those who adhere to them.” He also believed that religion was essential to social cohesion and social solidarity, and

in this manner he anticipated a functionalist view of religion. Bronislaw Malinowski also saw religion as promoting social solidarity but within an emotive context in which religious ritual was not so much about creating a solution to a crisis but instead was more about enhancing group solidarity in the face of crisis. He also saw religion as a powerful moral force, one that defined right conduct. In the same vein, Anthony F. C. Wallace, while emphasizing the role of religion as the fundamental societal force for social control, identity formation, and value definition, also portrayed it as a means by which social contradictions could be rationalized and justified. He also suggested that in some contexts, religion could be seen as a source of inspiration for social change. Clifford Geertz saw religion as a set of symbols that created “pervasive moods and motivations in men” that conceptualized the nature of existence. Finally, Maurice Bloch sees religion and politics inextricably intertwined across all levels of sociocultural complexity but notes that relationships among symbols, religion, ritual, politics, and action can be extremely complex. That is, a ritual event sanctioned by religious belief may remain constant and unchanging through periods of dramatic socioeconomic transformations. Here, religion may appear conservative, but through its use in novel and new contexts by emerging leaders, a traditional form is used to justify new social circumstances.

Summarizing these perspectives as well as those of other theorists of religion, it is possible to say that religion does at least the following: it provides an explanation for the existence of the world, its form, and content and the place of people within it; offers significant opportunity for

the development of a sense of group cohesion, social solidarity, or communal feeling, especially for the members of small-scale face-to-face societies; explains, at least in part, the nature of social relationships within and between societies and provides a justification for the shape of social norms and rules; creates an emotional and psychological context for the evaluation of daily experience and how it articulates with rules, roles, and norms; creates a basis for the formation of individual and group identity; identifies nonhuman actors as elements of existence and provides mechanisms whereby they can be addressed; creates a set of procedures or processes, such as ritual, that can be used to influence the course of events; presents a set of symbols—material, linguistic, and cognitive—that conceptualize, reflect, capture, and represent the nature of existence; and may become a kind of tool used by individuals to create new social and political spaces or resist their appearance.

If religion is primarily about ways in which to think about the world, ritual is seen as the vehicle used by religion to influence the world. Ritual is action and can be defined as a repeated patterned set of activities or sequence of events. If such activity is performed within the context of religion and manipulates or uses religious symbols, it is then possible to define this as religious ritual. Ritual that can be characterized as religious can be found in all societies, even those that have no formal concept of religion. Within a religious context, ritual is often closely related to myth, which can generally be seen as stories that societies tell about the origin and place in the world and that usually communicate important principles of conduct, behavior, and morality. In many societies, rituals enact aspects of these stories.

Religious rituals vary tremendously in scale. Some are conducted by single individuals in the privacy of their homes or in a sacred place, while others involve whole communities that have come together to perform a rite. Types of religious rituals vary as well. Anthony F. C. Wallace, an anthropologist, has classified religious rituals into at least six major categories, including so-called rites of passage, healing and therapeutic rituals (or those designed to cause harm to enemies), rituals used to control nature, salvation

rituals, revitalization rituals, and rites that are used to enhance social solidarity or remind practitioners of correct behavior and morality. Obviously, rituals can serve more than one purpose.

Defining Ritual and Religion

No known human culture lacks religious or ritual experience. Two signature threads may be traced through the history of anthropology's approach to religion. One, rooted in individual cognition, gives primacy to ideas, concepts, and beliefs. The other is grounded in ritual as the primary humanizing social experience and generator of the sacred domain.

A prime example of the first tendency was Edward Tylor's 1871 definition of religion as animism: belief in spiritual beings, arising from a concept of the soul. Herbert Spencer, James Frazer, and the naturist Max Müller followed this trend of ascribing religion to erroneous beliefs or pseudorational explanations. Rejecting notions of religion as the "product of a delirious interpretation," Emile Durkheim established the sociology of religion. His 1912 text *The Elementary Forms of Religious Life* remains the single most influential work on the subject.

For Durkheim, there were no false religions: all were rooted in reality and expressed that reality was, above all, "a system of notions by which individuals imagine the society to which they belong." Such a system could not arise from the thought or experience of any individual alone. Only through collective effervescence, the intense exaltation of experience in ritual, could individual members of a group become aware of their moral unity, allowing fusion of all individual feelings into a common feeling. Durkheim describes this process in materialist terms: collective representation requires consciousnesses to act on one another through tangible intermediaries. Individual minds can only

meet and commune by coming out of themselves through movement. “It is the homogeneity of these movements that makes the group aware of itself,” according to Durkheim. That homogeneity, once established, serves to symbolize the representations. Without these symbols, such feelings and representations cannot endure. The movements must be inscribed on “lasting things,” material objects or designs on the body that can embody the representations.

Durkheim’s fundamental idea is that religious phenomena set apart and oppose the sacred to the profane. In his definition, religion is “a unified system of beliefs and practices relative to sacred things, that is to say, things set apart and surrounded by prohibitions—beliefs and practices that unite its adherents in a single moral community called a church.” Ritual alone can provide the generative ground for experience of the moral community; the sacred objects that embody collective representations stand for nothing other than the community’s sense of itself. Durkheim’s work was cast as a study of supposedly “primitive” or simple religions, using ethnography of Australian totemism. But in principle he did not differentiate the sacred experience of an Aboriginal corroboree, with its collective effervescence engendered by bullroarers, from the political fervor of citizens marching under the revolutionary flag of the Republic.

Solidly within Durkheim’s tradition stands Roy Rappaport’s analysis of the form and features of ritual that make it “the social act basic to humanity” and Mary Douglas and Victor Turner’s investigations of the sacred in relation to social order. Where Durkheim had never allowed for conflict at the heart of his moral community, these anthropologists grappled with questions of deception and contest underlying society’s most basic truths. Ritual overcomes the divisiveness of individually held beliefs.

Turner’s ethnography of the Ndembu of Zambia vividly illustrated ritual as dynamic social drama, renewing the moral community through critical junctures of change and conflict within the group such as in a rite of initiation. Initiates, removed from the normal structures and categories of everyday life, enter a “realm of primitive hypothesis, where there is a certain freedom to juggle with the factors of existence.”

In this “liminal” phase, ritual initiates play with and reconfigures the symbolic building blocks of the cosmos, and the initiates are offered the opportunity to see their place within it.

Cognitive anthropologists Pascal Boyer and Scott Atran have recently rejuvenated the old Tylorian perspective. Religion emerges as an evolutionary by-product rather than adaptation. The religious universe is populated with counterintuitive entities resulting from cognitive misfires: in effect, our minds all too easily ascribe agency and intention even to inanimate objects and non-humans. These supernatural beings may then be recruited as a kind of moral police force against social defection. But this mentalist approach still falls back on Durkheimian mechanisms of ritual collective effervescence to render the “gods” morally authoritative. Atran concedes that the costliness of ritual participation is the way individuals demonstrate commitment to their group.

Seeing Ritual and Religion in the Archaeological Record

In the hierarchy of reliability in archaeological inference that the British archaeologist Christopher Hawkes presented in 1954, the reconstruction of technologies, subsistence economies, sociopolitical institutions, and religion are compared to steps on a ladder. This ladder model has become seminal and has remained anchored in archaeological thinking up to the present. According to Hawkes, seeing religion in the archaeological record is the most demanding task.

There are archaeologists who deny any chance of reliably reconstructing prehistoric religion. Seemingly, these scientists are not aware of the full range of their discipline. Archaeology has to do with what human beings produced and experienced in the past, that is, how they constructed their cultural space. Culture functions in a way whereby human beings make sense of the world by attributing meaning to the artifacts they live with. The artifacts constitute the visible dimension of culture, while the conventional meaning that is attached to them forms the invisible network of mentifacts (i.e., ideas and values). There is a pressing demand for archaeological theorists to reach beyond the technological and economic domains, and even beyond the social domain, toward a reconstruction of beliefs, values, and religious traditions.

For the world of antiquity and prehistory the significance of religion was much more comprehensive when compared with the more modern separation of the religious sphere from the secular. Societies with a prescientific worldview base their knowledge about their environment and about their place in the world on mythopoetic concepts. When we modern observers try to reconstruct the spirited world of the past with our science-oriented categories and nomenclature, we are advised not to impose modern conceptualizations, which were nonexistent in ancient times.

Similar reservations hold true for the Euro-American tradition of thinking in opposites. When archaeologists describe the living conditions of prehistoric communities, they easily adhere to a framework of opposite concepts known from our world. As an example, the prominent items of imagery at Çatalhöyük in southern Turkey (ca. 7400 to 6000 BCE), the so-called splayed figures, in bas-relief on the walls of sanctuaries can be mentioned, which were interpreted by the excavator in the 1960s, James Mellaart, as images of the Great Goddess of Anatolia. More careful investigation has revealed that the feet and hands may have been depictions of bears' claws. The conclusion is that since the figures show animal features, they cannot be images of a divinity.

Such thinking in opposites misses the crucial point that different types of hybrid figures are known from prehistoric cultures, from Eur-

asian imagery for one (e.g., a female figure with arms like birds' wings, with legs like those of a bear, with hands like eagles' claws, and with a lion's head). The hybrid figures of Egyptian divinities, both anthropomorphic and zoomorphic, are well known. In Homer's *Iliad* (eighth century BCE), the goddess Athena is described as "owl-eyed." The name of the goddess Artemis is associated with the Greek term for bear (i.e., *arktos*). Artemis is the Divine Bear Woman. Ideas about the kinship of humans and revered animals crystallize in totemism, a theme of larger coinage that is of high age and features in many mythological traditions around the world, past and present. It is obvious that the categorical distinction we make between what is human and what belongs to the realm of animals was unknown to people in prehistory.

Many of the problems involved in interpretative approaches to prehistoric religion arise from the fact that there are no written records that would contain information and descriptions of religious practices. The presence of ancient texts explaining Greek mythology makes the identification of rituals within the context of the archaeological record much easier. Despite the difference between ancient civilizations with written media and prehistoric cultures without such media, Greek archaeology teaches us the valuable insight that myth and religion were integral elements of Greek art. Why would prehistoric imagery be less religious than that of ancient Greece?

Religion is a complex system of values, rituals, and ceremonial activities, such as rites of passage (e.g., baptism, marriage, and funerals), processions, offerings, and festivities. Every complex system has a multilayered infrastructure, which means that the nature of prehistoric religion cannot be identified on the basis of any single artifact. In order to gain knowledge about an artifact's significance for the mythopoetic conceptualizations of ancient cultural memory, we have to look at the context in which the artifact is embedded. A figurine is an artifact by definition because it is made by a human being, and it establishes a meaningful role in relation to other artifacts of the same cultural horizon that, together, form a system of interrelated meaningful items. The context in which this artifact appears may be a cult platform in a sanctuary or

near the hearth of a house and may point to a ritual and/or ceremonial function. And yet in order to determine the exact nature of a ritual, we have to relate to a working hypothesis about beliefs and values among prehistoric people. Therefore, the assumptions about the religious system and the identifications of its rituals are intrinsically intertwined. In any statement about ritual in prehistory, a statement about the religious system is involved, either explicitly or implicitly.

The terminological apparatus that is applied to reconstruct a prehistoric worldview may pose challenges to the investigator. For example, it is widely agreed to see the function of female figurines in general association with religious beliefs. What is more tricky, is how to identify the religious function of the figurines more precisely. If they are seen as images of a goddess, such an identification may evoke misleading (albeit unwanted) allures to the concept of “goddess” as we know it from antiquity. Antique goddesses are individualized as personified characters identified by specific names and attributes described by classical authors and known from early inscriptions. Many of these goddesses, while retaining various aspects of their ancient roots, function within the power structure of hierarchical pantheons.

In contrast to goddesses of the historical periods, the concept of a prehistoric divinity may

be defined as “a symbol of the unity of all life in Nature.” Such an encompassing concept leaves space for an overall view on the natural world. When viewing female figurines as spirit holders of an overarching concept of divinity, then the modern observer may find access to the mind-set of people in a spirited world.

Given the complexity of reconstructive work to explore prehistoric religion, an interdisciplinary approach, reaching beyond the boundaries of archaeology, is called for. In addition to archaeology as a discipline “of the spade,” the history of mythology and religion (i.e., archaeomythology), culture science, semiotics, and cognitive science have also made valuable contributions to the study of prehistoric religion.

■ Introduction: Religious and Ritual Practice until 15,000 BCE

Although religion and ritual are notoriously difficult to define in the archaeological record, it is possible to use analogy and ethnoarchaeology, along with the materials recovered from a number of sites ranging from Africa to Europe, to infer what they may have been like during the early evolution of our species. However, it is important to acknowledge that much of this discussion will be little more than plausible, informed speculation that will be difficult to verify.

Although many animals reflect some degree of self-awareness (i.e., chimpanzees, elephants),

it is probable that *Homo erectus* is the first member of our evolutionary lineage that had a degree of self-awareness more similar to that of our species than that of its predecessors. This assumption is based upon multiple lines of evidence, including a wider cultural repertoire (habitual use of fire, complex settlement patterns), movement into a wide range of new ecological niches, and evidence of careful attention to the details of tool production, such as the obvious symmetry of Acheulean hand axes and other complex tools of this era.

A striking discovery from a number of sites in East Asia, Africa, and Europe dating from 900,000 to 400,000 years ago is the number of human bones, especially skulls that were intentionally cut, crushed, or broken. At the famous *Homo erectus* site of Zhoukoudian, a number of skulls with their bases smashed in and removed is suggestive of the removal of the brain in a cannibalistic act. Acts like these have led Brian Hayden to suggest that they reflect a clear sense of the afterlife and possibly the soul. Using analogy, he notes that modern cannibals break skulls in a similar manner and consume the brains as part of a ritual act to capture the essence of the deceased. Not surprisingly, his interpretation of these remains has been challenged, but his argument is plausible. If accepted, these activities can certainly be seen as an early form of ritual within a religious context.

There seems to be little doubt, however, that Neanderthal-era burials reflect a sense of afterlife, and the formal treatment of the dead by placing them into specially excavated pits (what we would call graves), the placement of objects with the deceased (like the plants at Shanidar), and the use of red pigments at a number of sites supports this argument. Analogy strongly suggests that these interments were performed within some kind of religious context. The elaborate burials found throughout the Upper Paleolithic in many parts of the world demonstrate the continuity of this belief in an afterlife.

Although it is widely known that anatomically modern humans were responsible for painting the remarkable art found in the deep caves of western Europe after 50,000 years ago, it is less well understood that Neanderthals also explored many such caves and performed rituals within them. Again, while the evidence for these activities is controversial, the arguments for them are quite plausible. French archaeologists have documented a number of small structures, some made out of stalagmites, in caves that were occupied in Neanderthal times as early as 50,000 years ago. At the most reliable of these sites, the entrances to the caves had been blocked in modern times, thus rendering it unlikely that these sites were created by Upper Paleolithic humans who entered the region after 40,000 years ago. The location of these small structures deep

within the caves suggests to some anthropologists that they were the scenes of ritual activity, possibly initiation rites. There are also arguments for the existence of animal cults, specifically related to cave bears, in Neanderthal times. Although many early reports of such cults have been dismissed with good reason by archaeologists, more recent findings, such as the burial of a cave bear near the burial of a Neanderthal at the site of Régourdou in southwestern France, have reopened the debate.

It is only after 40,000 years that the evidence for ritual and religion becomes clearer. Although there are many debates as to the meaning of the art painted on the walls of caves such as Lascaux, Altamira, and Chauvet, there is little question that the images served a ritual purpose that was embedded within a poorly understood religious tradition. David Lewis-Williams has argued that many of the images seen on the cave walls are a reflection of shamanic practice, a common form of ritual activity among hunters and gatherers. Lewis-Williams argues that certain geometric shapes, such as dots, zigzags, concentric lines, and other forms, represent what are known as entopic images. These appear in the human visual field under conditions of stress and sensory deprivation. In his reconstruction, a shaman would enter the caves and perform rituals and later would inscribe his visions on the cave walls. Other images, such as half-human, half-animals, suggest a magical transformation of the shaman during these rituals. The images of the animals themselves, such as the bison, mammoth, horse, and others, have been interpreted as evidence for animal cults.

Another artifact from the Upper Paleolithic—the Venus figurine—has also been the focus of intense debate as to its meaning and role within a ritual or religious belief system. These figures, carved out of stone but sometimes ivory, have exaggerated hips, breasts, and buttocks. However, their faces are curiously blank, with no signs of eyes, nose, or mouth. Because of a lack of facial features, they are not thought to be representations of any person. Most anthropologists believe that these figures are meant to symbolize female fertility, and Brian Hayden has argued that they served as a part of a fertility cult in high-status or prestige families. Others

have suggested that this figure was meant to represent a female goddess, but these arguments have been widely discounted.

Although it is likely that many of the interpretations of these contexts and artifacts are plausible, it remains the case that we will never be certain of the meanings that they carried for the peoples who created them.

Primate Attitudes toward Death

Primates respond to death in a variety of ways. Any examination of nonhuman primate attitudes toward death will necessarily be speculative, and the danger of anthropomorphism, which is interpreting animal behavior using human categories, will always be present. Humans, *Homo sapiens*, display the widest variety of responses of any primate toward death. Human cultures have historically responded to death in religious ways, involving complex webs of social interactions, mourning, and rituals. Evidence for hominid concern for the dead exists as early as the Neanderthals, who buried their dead.

The evidence is more difficult to ascertain when considering nonhuman primate attitudes toward death. Attitudes or responses to death in nonhuman primates arguably can be understood as part of the broader category of primate culture. Strong evidence exists for culture in primates, particularly in the genera *Cebus*, *Gorilla*, *Macaca*, *Pan*, and *Pongo*. Genus *Pan*, which includes chimpanzees and bonobos, by far demonstrates the most evidence for culture. This genus has been the richest source thus far for discovering responses to death.

Although it is difficult to universalize primate attitudes toward death, primatologists have observed a number of responses among chimpanzees, for example. In response to the death of their mothers, chimpanzee infants have been observed displaying similar body language to that of human children under similar circumstances.

In at least one instance, a chimpanzee child died shortly after its mother's death. Likewise, chimpanzee mothers commonly respond to the death of an infant by whimpering and wailing. On occasion, chimpanzee mothers have been observed to scream when their children die. Chimpanzees have also been observed screaming in response to the death of a companion, while at other times they remain silent for long periods of time. In one instance of accidental death of an adult chimpanzee, the remainder of the pack gazed upon the carcass, threw rocks in a variety of directions, and embraced one another, and some even touched and sniffed the carcass.

Responses to death in monkeys have been equally varied. In captivity, infant monkeys have been observed making a ruckus when their mothers have been taken away, whether for purposes of experimentation or because they have died. In some instances, infant monkeys respond to maternal death by losing their appetites and slouching, becoming nonresponsive. Likewise, in response to the death of captive infant rhesus macaques, some mothers have made vocal noises for an entire day after the dead child has been removed. In one instance where a baboon lost her infant, the mother appeared agitated in the weeks following the death in that every time the troop passed by the site of the infant's death, the mother was seen looking for her infant, calling out loud, and sometimes climbing a tree.

Anthropological Thinking on Death and Burial in Simple Societies

The anthropology of death examines the conceptualization of death in societies and the social rituals created to commemorate the deceased. Anthropological thinking in regard to the dead and burial practices in simple societies involves the examination of how cultural definitions of death shape how such societies deal with the process of dying and burial. Biological definitions of death, or the termination of life and/or the life cycle, have far deeper meanings given the cultural constructs imparted by simple societies related to specific worldviews, religions, and other belief paradigms. The characteristics of ceremony and rituals and the process of burial and mourning differ from culture to culture regardless of the level of complexity of individual societies. Moreover, anthropologists have found that there are no universal conceptualizations of death; however, there are rather culturally specific definitions that characterize how different societies deal with the deceased, thus moving away from Western assumptions that all people view death similarly.

Anthropologists who study death and burial in simple societies examine the social and cultural practices surrounding the death of individuals. Through the examination of the differing conceptualizations of death and dying, grief and mourning, burial rituals, and commemorative practices surrounding the deceased, anthropologists can decipher how such practices are social constructions specific to unique cultural contexts. Anthropologist Bronislaw Malinowski examined the relationship of burial customs to beliefs about transcendence beyond death in simple societies. His examination on the rela-

tionship of rites surrounding death and burial considered how religion or understandings of the life cycle served to explain death as part of the life cycle and how burial provided a mechanism for this process and understanding of human immortality. Moreover, it provided a venue for mourning, reverence, and restoring normality after the social disruption caused by death created within the group. Anthropologists who examine death and burials in simple societies have also studied how some groups view death as the end of the life process, while others might see it as a regenerative process that continues in either an afterlife or another stage of the life cycle. The way these groups ritualize dying, death, and burial is indicative of these sometimes subtle differences.

The anthropological study of death in contemporary simple societies offers a glimpse into the greater development of the process of death and dying and how these are conceived of in more complex societies in similar ways. However, the rituals surrounding such practices are far too diverse for anthropologists to establish universal human conceptualizations of death and the idea of an afterlife. Moreover, archaeological evidence of early human societies offers illustrative evidence that such practices date back to early humans as well as to Neanderthals. Such evidence suggests that burial practices on the part of such early hominids are indicative of the growing complexity of their belief systems and their understanding of death as a social process related to the group, be they relatives or members of the greater community.

Disposal of the Dead by Our Earliest Ancestors

The identification of burial practices for our earliest ancestors is a controversial topic. While some form of disposal of the dead has been

Neanderthal burial from Kabara Cave, Israel, 60,000 years old. The body appears to have been intentionally buried, having been laid on his back in an east-west orientation (head facing west). Excavators found that his right arm was laid across his chest and his left arm on his stomach. (The Natural History Museum, London/The Image Works)

hypothesized for Neanderthals, little is known for any other previous hominin species. The main obstacle impeding a better understanding of burial practices before 100,000 years ago remains the differential preservation of organic materials over time as well as the action of taphonomic processes and natural agents that have affected the composition, location, and overall integrity of the fossil record after its initial deposition in the ground.

The oldest burials are therefore commonly attributed to Neanderthals around 100,000 years ago, as documented at the sites of La Chapelle-aux-Saints (France, 1908) and Shanidar Cave (Iraq, 1971). While the real meaning behind these burials is still a debated topic, it is safe to assume that these burials were intentional even though intentionally does not demonstrate their religious or supernatural nature. They are best described as shallow round pits where the deceased was often placed in a forced-flexed or fetal position. Some of these bodies were covered with a red pigment identified as ground ochre (iron oxide). The specific meaning of these practices is unknown, but they may reflect some form of ritual. While some archaeologists would

like to see Neanderthal burials as the first signs of religious thought, most archaeologists are much more skeptical. The quick disposal of rapidly decaying bodies may have been a much more practical justification for such practices.

After 35,000 years ago and the demise of the last archaic hominin species (Neanderthals), burial practices associated with our species became much more sophisticated. Grave goods such as jewelry and carved objects are often found in long narrow graves. These burials clearly reflect the investment of the group in rituals likely supported by some form of belief in the supernatural.

Treatment of the Dead in Neanderthal Times

The existence of intentional burials associated with Neanderthals is still a controversial topic in archaeology. The difficulty for archaeologists in reaching a firm consensus on this topic stems from the fact that the data used to support intentional burials and the existence of rituals associated with these burials remains ambiguous. It is, however, commonly accepted by most archaeologists that Neanderthals were the first hominin species for which we are able to document some form of disposal of the dead. The very fact that we possess more Neanderthal complete specimens than any other previous hominin species tends to support the notion that Neanderthals buried their dead. The controversial nature of this topic is also reinforced by current debates within the archaeological community regarding the cognitive capacities of Neanderthals and their evolutionary relationships with our own

species (*Homo sapiens*). A total of about 33 Neanderthal burials have been recorded to date.

The first Neanderthal burial was discovered in 1908 by two local French archaeologists at the site of La Chapelle aux Saints in western France. The archaeologists claimed to have found a complete skeleton belonging to an old Neanderthal male placed in a shallow round pit covered with a red pigment identified as ground ochre (iron oxide). Based on their account, the skeleton was in a forced-flexed, or fetal, position lying on his side and surrounded by large animal bones and stone tools interpreted as grave offerings. In 1909 a Swiss collector made a similar discovery at the site of Le Moustier (France). He also described the Neanderthal individual as a male skeleton in a forced-flexed position covered with red ochre. In the 1920s the excavation of the rock shelter of La Ferrassie (France) yielded eight Neanderthal skeletons (two adults and five children, including two neonates), which were described as having been buried in small round shallow pits. A slab of limestone located on top of one of the children burials was interpreted as a possible tombstone since it bore geometric engravings (grooves and cupules) although later identified as resulting from water dropping on the stone from the ceiling of the shelter. The site of La Ferrassie remains one of the most important archaeological sites supporting the existence of burials during Neanderthal times. In the late 1950s American archaeologists discovered nine Neanderthal skeletons at the site of Shanidar Cave in the Kurdistan region of northern Iraq. All the individuals were in a forced-flexed position on their sides or on their backs, bringing further support to the intentionality of Neanderthal burial practices. The unusually high concentration of flower pollen in the soil surrounding one of the male skeletons (Shanidar 4) was interpreted as resulting from a funeral ritual. However, this hypothesis was later rejected by some archaeologists who demonstrated that the flower pollen may have been brought into the burial by natural agents (wind and rodents). In 1954 the site of Regourdou (France) yielded one Neanderthal skeleton in proximity to cave bear skulls. The excavator of the site claimed that the cave bears were painted with red ochre and placed in a coffin made out

➤ SHANIDAR CAVE

The site of Shanidar Cave is a large Paleolithic site located in the Zagros Mountains of northern modern Iraq. Excavated by Ralph and Rose Solecki from 1957 to 1961, the site's stratigraphic sequence covers the Middle and Upper Paleolithic all the way to the Pre-Pottery Neolithic (from ca. 80,000 to 10,600 BP). The most important archaeological features are a series of nine nearly complete Neanderthal skeletons, while a tenth individual was recently found by M. Zeder. One of these individuals (Shanidar 4, discovered in 1960) was identified as a potential burial. The skeleton belonged to a 30–45-year-old male lying on his left side in a forced-flexed or fetal position. The analysis of samples of the soil directly surrounding the skeleton revealed an unusually high concentration of flower pollens. Some of these plants were further identified as possessing medicinal properties, leading to the hypothesis that this so-called flower burial was possibly one of a shaman or healer. This hypothesis was later challenged and refuted by archaeologists demonstrating that these pollens have not necessarily been brought to the site by Neanderthals but by natural agents including a small rodent (Persian jird) known to have burrowed through the site.

of flat limestone slabs. Since the excavation of the site did not follow strict scientific guidelines, it is difficult to evaluate the real relationship between the Neanderthal fossil and the cave bears.

The difficulty in identifying rituals associated with Neanderthal burials stems from the very nature of the archaeological record. Typically, the burials have been found at large cave sites where Neanderthals carried out their daily living activities. These archaeological sites thus contain large numbers of stone tools and animal bones as well as hearths and other archaeological features. It is difficult to clearly establish that the objects found near the burials were indeed offerings rather

than normal remains from Neanderthal occupation of the site. Similarly, the presence of large slabs of limestone interpreted as tombstones on top of some of the Neanderthal burials are to be expected in rock shelters and cave sites. Large portions of the cave roof regularly collapse due to erosion, the effect of infiltrated water, and expansion during glacial conditions that eventually crack the cave walls. Similarly, the forced-flexed position observed for many of the Neanderthal skeletons was interpreted by some archaeologists as reflecting specific burial practices and/or religious or supernatural beliefs. Other archaeologists have pointed out the fact that flexing a corpse into such a position could have been a way to minimize the space taken up by these burials, which were located in the middle of their living quarters. Such practices are still widespread in many cultures around the world today.

De-fleshing and possibly the cannibalistic consumption of the deceased flesh may be another mortuary ritual practiced by Neanderthals. At several archaeological sites in Europe, cut marks left by stone tools were identified on many Neanderthal bones. At the site of Krapina (Croatia), for example, these stone tool marks were located on the skulls and skull fragments of several young Neanderthal individuals. Similar evidence was identified at the sites of Abri Moula (France), Grotta Guattari (Italy), and Combe-Grenal (France). It is again difficult to further evaluate the significance and the actual function of such cannibalistic practices. The ritualized consumption of human flesh has been well documented in modern-day tribal groups in Africa and in the Pacific Islands. However, such practice has become relatively rare since it has been shown to cause Kuru or Creutzfeldt-Jacob disease in some members of those populations.

Death and Early Modern Humans to 15,000 BCE

Archaic *Homo sapiens* ("early modern humans") appear in the fossil records of Africa, Asia, and Europe between approximately 400,000 and 200,000 BCE. At this time, they began to exhibit ritual activities that seem to connect the living with the dead. From 130,000 to 28,000 BCE, changes in skeletal morphology (Neanderthal in comparison with *Homo sapiens sapiens* remains) and an increase of ritual practice suggest not only biological evolution and an increase of knowledge about the physical environment but also the possibility of symbolic thought pertaining to death. By 13,000 BCE our species initiated the process of the domestication of plants and animals, which led to the Neolithic age (10,000–4000 BCE). Apparent continuity exists among mortuary ritual traditions of archaic *Homo sapiens*, Neanderthal, modern *Homo sapiens sapiens*, and Neolithic populations.

As early as 200,000 BCE, burial of humans becomes deliberate and ritualistic in scope, as evidenced by the manipulation of human bodies after death. At the Spanish site of Sima de los Huesos in Sierra de Atapuerca (dated to approximately 200,000 BCE), physical anthropologists analyzed the remains of a communal grave to find that prior to deposition of the corpses the flesh had been removed from the skulls, indicating symbolic behavior connected with burial. At Kebara Cave in Israel, archaeologists found that the focus of mortuary practice continued to be the skull 130,000 years later (70,000–60,000 BCE), finding that a carefully positioned skeleton had been decapitated, its skull deposited elsewhere.

Another indication of ritual continuity was the widespread use of red ocher at many burial sites as early as 150,000 BCE. Ocher is formed of deposits of the mineral iron oxide, which can be grated to create powder. This substance was of

ten sprinkled over the dead prior to burial in Africa, Asia, Europe, and North America. In Australia, archaeologists uncovered skeletons having ochre sprinkled over them in graves dating to approximately 60,000–40,000 BCE. Among North American indigenous populations, the practice continued into historic times. Anthropologists speculate that red ochre symbolized life and therefore the life force to early humans. The act of sprinkling ochre over the dead may indicate the conceptualization of a life after death. However, the use of red ochre may also indicate growing knowledge of the physical world. In this regard, certain Australian indigenous tribes in the present treat wounds with ochre because of its antiseptic qualities, and we know that growing knowledge of medicinal herbs was a particular feature of Neanderthal culture.

The site most famous for Neanderthal burial is Shanidar Cave in Iraq. A skeleton of a man had been buried in a pit at the back of the cave (approximately 60,000–40,000 BCE), his body carefully positioned. Pollen analysis revealed that the corpse may have been placed on a bed of flowers, and a wreath of flowers was placed upon its head. All of the flowers are known to have had medicinal properties that are still utilized by herbalists today. There are critics of this forensic data who maintain that botanical remains probably did not represent deliberate burial custom. Rather, the pollen is interpreted as having entered the cave by means of air currents or the activity of rodents. However, the evidence for the existence of a wreath of flowers and medicinal herbs (to the exclusion of other plant pollen) makes the air-current and rodent hypothesis a bit doubtful as well. In any case, if the body had been buried with flowers, a great antiquity for funerary flower offerings may be suggested.

Since the excavations at Shanidar Cave, thousands of Neanderthal graves have been discovered from the Middle East to Russia. Some of the most important sites include Skhul Cave (Mount Carmel) and Kebara Cave in Israel; La Ferrassie, La Chapelle aux Saints, Le Moustier, and many others sites in France; the Neander Valley in Germany; Grotta Guattari in Italy; Zafarraya in Spain; Krapina in Croatia; the Mesmaiskaya Cave

in the Caucasus of Russia; and Teshik Tash in Uzbekistan. Two significant aspects of the data collected from these archaeological sites deserve mention. First, there was evidently culture contact between Neanderthal and Cro-Magnon populations. In at least one excavation at the Jebel Qafse site in Israel (dated to 100,000–90,000 BCE), a communal grave of 21 individuals included *Homo sapiens sapiens* and at least 1 Neanderthal. Second, both populations buried their dead with grave goods, for they are found in roughly half the burials whether of Neanderthal, Archaic *Homo sapiens*, or *Homo sapiens sapiens* origin. Interred artifacts include tools and other objects made of stone, bone, and antler as well as pierced shells, teeth, stone pendants, and other sorts of adornment. At the Qafse site, excavations in 1971 uncovered the skeleton of a child buried in a shallow pit, positioned on its back with both hands placed near the head, one hand holding a deer antler. Some archaeologists and paleoanthropologists speculate that such artifacts may imply the beginning of social inequality, while others hypothesize that the presence of grave goods is evidence of a belief in life after death. This practice of burying bodies with jewelry, tools, and other objects for the afterlife had its greatest elaboration in ancient Egypt during historic times, but evidently its roots have a much greater antiquity.

Death and Burial in the Upper Paleolithic

Intentional burial on the part of early humans suggests to many archaeologists that hominids during the Upper Paleolithic (approximately 40,000 to 10,000 years ago) had a particular

► THE SUNGIR BURIALS

The Sungir site (near the city of Vladimir, central Russia) is attributed to Kostenki culture and is dated between 20,000 and 26,000 years ago. A complex burial was found near one of the dwellings at the site, and it contained a young girl of 7–8 years and a boy of 12–13 years (both defined as anatomically modern humans). They were buried simultaneously, back-to-back, in a narrow grave that showed evidence of fire and the abundant scattering of powdered red ochre.

One of the most striking peculiarities of the burial is the presence of a wide variety of artifacts, including highly decorated clothing and head-dresses. Almost 7,500 mammoth tusk beads used to decorate the clothing were recovered. Carved disks made of mammoth tusk were found at the right temple of both individuals and on the girl's chest and stomach. Other adornments associated with the girl included lamellate and bead bracelets, finger rings, tiepins, and other carved artifacts of ivory and bone. Two *batons de*

commandement (animal bones thought to have been used as spear shaft straighteners) were found next to the girl's feet.

Two long spears made of straightened mammoth tusk as well as flint knives were found next to the boy. Other artifacts found near him suggest their use in an animal cult. These include horse figurines found on his chest, a small sculpture of a mammoth found behind his left shoulder, two cave lion claws near his mouth and waist, and an imitation animal tail made of flattened squarish bone beads behind his torso.

The significance of the Sungir children's burial lies in the elaborate treatment of the dead. Although burials are known from earlier time periods, these burials suggest a well-developed sense of ritual and religion in these Upper Paleolithic peoples. Moreover, children were rarely buried with such an abundance of artifacts, and this implies that in some sense, they were perceived as special or important within their society.

—Olena V. Smyntyna

conceptualization of death. Moreover, intentional burials perhaps also illustrate that as early human societies developed increasingly complex cognitive abilities, they were also establishing particular views regarding life and death. Through evidence gathered in archaeological sites, such as grave goods, ochre dyes, and the actual burial site itself, archaeologists have interpreted that these early burials are indicative of awareness of death and are perhaps an early development of belief systems surrounding immortality. While much of this theoretical perspective is purely speculative given the available evidence, it does offer a glimpse into the early establishment of hominid ways of thinking surrounding death and dying and the increasing complexity of their lifeways in the Upper Paleolithic.

Archaeological evidence indicates that hominids did intentionally bury their dead in the late Middle Paleolithic, albeit in few findings. Intentional burial, replete with symbolic value given the burial goods, occurred during this period as *Homo sapiens* replaced Neanderthals. Moreover, this is illustrative of a long-term development

that lasted into the transition into the Upper Paleolithic. Regardless of the short span of time in which *Homo sapiens sapiens* (modern humans) and Neanderthals coexisted in Europe, early humans developed burial rites and funerary practices from which anthropologists derive that they were developing a more complex understanding of death. Regardless of the scholarly debate over the dispersal of *Homo sapiens* out of Africa, archaeological finds do illustrate that it was during the Upper Paleolithic in Europe that intentional burial became prevalent and a standard practice in early human societies.

The use of burial ochre, which was used to cover the corpses, was used by Neanderthals from the late Middle Paleolithic to the Upper Paleolithic. Modern humans also used ochre in burials down through the Neolithic period. Some archaeologists speculate that perhaps the reddish color of the ochre was akin to blood and was somehow associated with preservation of life. The early Cro-Magnon burials found at St. Eyzies in France in the mid-nineteenth century were illustrative of early intentional burials by

hominids. These Aurignacian culture intentional burials, replete with material goods indicative of early European *Homo sapiens sapiens*, offered archaeologists the first glimpse of human burials. At the Grimaldi caves on the French-Italian border, the remains of two children were discovered with elaborate decorations composed of seashells and animal teeth. The quality of the craftsmanship in the constructing of these complex decorations indicates to archaeologists that some meaning was given to the burial by the inclusion of such goods.

At Aurignacian culture burial sites found at Sungir in Russia, dated to the estimated range of 30,000 to 25,000 years before the present, five remains were found with a large amount of grave jewelry attached to the individuals. Pendants, necklaces, bone/tusk artifacts, and pierced beads were part of the findings. Given the amount of time and effort made at preparing this burial and the significance attached to these valuables, it can be suggested that perhaps this ritual formed a part of early human belief systems. Archaeologists interpret this as either a form of appreciation of the passed or the belief of a continuity of the life cycle in which the deceased should be properly clothed. Further findings from the subsequent Solutrean and Magdalenian epochs illustrate far more complex and elaborate burial rituals and grave goods and even artwork, suggesting that human societies had established belief systems surrounding an afterlife and perhaps also illustrating their understanding of the significance of death. In some regards, this understanding of death might have been the continuity of life in some other form or perhaps simply an understanding of the end of life and an appreciation for the deceased through a ritual. These are the explanations and interpretations by anthropologists, given the grave decorations and luxury goods found with early human remains in intentional burials. By the Neolithic, these practices were long established and part of the lifeways of myriad peoples throughout much of Afro-Eurasia.

Shamanic Religion in the European Upper Paleolithic

The concept of "shamanic religion" suggests an association to a belief system that we modern people categorize as one among the world's religions. As is the case with various other religious systems, there is more to shamanism than cult practices and ritual ceremonies. Shamanism has an infrastructure, and this is comprised of value systems and a worldview that serve as guidelines for a certain way of life. In order to emphasize the overarching role of shamanic worldview for the people who profess it, the term "shamanhood" is preferred over the term "shamanism" by some scholars.

Shamanism (or shamanhood) is perhaps the most widespread prescientific worldview in the cultures of the world, past and present. With respect to Eurasia and its ancient convergent cultures, shamanism is indeed the key to the understanding of how belief systems are over-arched by an animistic worldview. Anthropologist Antero Kare states, "The most ancient, the oldest and the most long-lasting [*sic*] institution in the northern hemisphere is shamanism. Shamanism is a family—a clan—institution and it has been present in hunting, gathering and agricultural societies right up to our day, living on in the industrial era."

The oldest record written by a European in which reference is made to shamanism in Siberia comes from the late seventeenth century CE. The word "shaman" in European languages is borrowed, via Russian, from a Tungus language. In a Chinese source of the twelfth century CE, we learn that Tungus *saman* originally meant "female shaman." The earliest reference

to shamanism among the Tungus (Jurchen) is found in a Chinese source dating to the seventh century CE.

The spiritual motivation of a shamanistic worldview lies in the necessity of a harmonious relationship of human beings with nature. One aspect of a shamanistic worldview is the awareness about the fragile balance of life resources that enhances the insight that the living conditions and activities of human beings cannot evolve in a kind of antagonistic tension with the life cycle but instead evolve in concordance with it. Human beings are supposed to live and breathe in the rhythm of nature in order to minimize conflict when interacting with the world of animals, plants, and the spirits.

Since its appearance as a cultural institution among Paleolithic hunter-gatherers, shamanism has persisted in many parts of Eurasia, and as a living institution, it can be studied in the Himalayas, Southeast Asia, Mongolia, Siberia, and the northeastern corner of Europe (among the Nenets/Yuraks). Among the Sami people of northern Scandinavia, animistic beliefs are still vivid as part of cultural memory and in local lore. Among the native peoples of northern Siberia, shamanism has enjoyed an unbroken continuity since the Ice Age. At that time, the arctic tundra stretched across the whole of Eurasia, from the Atlantic in the west to the Pacific in the east. Historical evidence illustrates that the shamanistic worldview that still today determines the pace of life among people in the Far North is the only viable guarantor of sustainability for community life near and in the eternal ice.

In a world of animated nature, the shaman possesses a key role for communication between the worlds as a mediator to convey the vital spiritual needs of the community to the forces that guarantee a harmonious balance among the participants in the life cycle. The shaman acts as a mediator between the world of the living and the spirit world with a mandate from the spiritual powers that inhabit the animated world. Only with the shaman's intervention can the community experience the oneness of the spirit world and the protection provided by the spirits inhabiting everything in the environment (plants, animals, and natural phenomena such as rivers or lakes, mountains, and the forest).

The tradition of shamanism among the peoples of northern Eurasia includes both male and female shamans. Female shamans among the Saami and the Samoyed peoples of Siberia were held in high esteem. Those traditions must be of great age, because there is evidence for the presence of women in the Neolithic imagery of northern Europe relating to mythopoetic contexts of shamanism, among them the image of a female shaman that features in the largest picture complex of rock art found thus far in Finland, at Astuvansalmi (in the municipality of Ristiina) on the shore of Lake Saimaa. The female shaman holds a bow, perhaps suggesting that the petroglyph depicts a female hunter. The figure is centered and surrounded by elks, with their heads turned toward her. The site has been identified as a cult place for the performance of rituals related to hunting magic. In all probability, the female figure who is depicted represents the performer of such rituals.

Cave painting and mobiliary art are the preferred genres of how the people of the Paleolithic expressed their worldview in visual form. Pictures and abstract motifs were painted on the walls of many caves, both in western Europe (in southwestern France and northern Spain) and in eastern Europe (in the Ural Mountains). Those who painted the caves had exceptional artistic skills, and it is assumed by some scholars that they were shamans. The images of animals and mythical beings are often aligned in narrative sequences whose contents remains cryptic to the modern observer. For the understanding of Paleolithic people the images had a meaning, most probably associated with rites of passage that were performed in certain areas of the caves, which served as sanctuaries. The action of painting was, most likely, a performance carried out in an altered state of consciousness (i.e., trance), which also activates mental imprints of elementary visual motifs such as dots, circles, grid signs, or wavy lines. Such motifs are found in association with naturalistic pictures. The oldest paintings in the caves date to a time prior to 30,000 BCE, and the youngest dates to circa 14,000 BCE.

In the Paleolithic imagery, one finds some specimens of figures with both anthropomorphic and zoomorphic features. A shamanistic context seems to be the only reasonable expla-

nation for these hybrid creatures, which are interpreted as shamans in ceremonial action. Among the most impressive of these images is the “deer-man” (known as the “magician”), from the Cave Les Trois Frères (Département Ariège in southern France), dating to some 13,000 years ago. Much older is the sculpture of the “lion-man” (a human figure with a lion’s head and feet) from Hohlenstein-Stadel in southern Germany, the age of which is circa 30,000 BCE.

The Paleolithic communities of Europe shared a remarkable degree of conformity in their cultural expression during the Gravettian period between 27,000 and 19,000 BCE. It can be conjectured that a shamanistic worldview formed part of the sociocultural network that united western Europe with Ukraine and Russia. Diagnostic items of the widespread Gravettian culture are female figurines of similar posture and style. During the transition from the Paleo-

lithic to the Mesolithic and Neolithic, shamanism gradually disappears from the record of western Europe but persists in northeastern Europe into subsequent historical periods.

■ Introduction: Ritual and Religious Beliefs, 15,000–4000 BCE

After 15,000 BCE, traces of what can be called religious activity become more apparent. In great part, this is due to the increasing complexity of society. In general, as society becomes more complex so does religion, and religion begins to assume a wider range of societal roles. Although its traditional roles, such as healing and promoting a worldview, are maintained, they begin to appear in new structures. A wider range of religious specialists can be found, and by the end of the era it is reasonable to describe these roles as priests. And while there may be private or family-level religious practice, by the end of the era religious ritual becomes increasingly institutionalized and supported by the secular rulers of more complex societies.

Certain regions are more precocious than others in these developments. We see a more formal expression of religious activity first in the ancient Near East at sites such as Göbekli Tepe, where large carved stones are erected. But no large monumental constructions can be found in

this region until the very end of the era. Elsewhere, religious activity, while more formal, has not yet achieved a true institutional role.

The Organization of Religion in Sedentary Societies

Sedentism generally precedes and predates the socioeconomy of plant cultivation. Sedentary lifeways enhance the transition to food production in the form of horticulture on a small scale and as agriculture on a larger scale. Sedentism is no natural stage in human social evolution. Yet socioeconomic conditions in mobile bands of archaic hunters and gatherers may lead to the transition from a nonsedentary lifeway to sedentism.

On the other hand, it would be incorrect to state that this transition was the result of intentional planning. The transition to sedentism was a multifaceted process in which external factors and human adaptive skills operated in succession.

The earliest signs of a trend toward sedentism are found in the ancient Near East in the context of ecological changes that affected human living conditions. When the climate became colder during the Younger Dryas phase (in the course of the twelfth millennium BCE), this affected the availability of seeds of wild grass and other food crops, then an important food resource for the hunter-gatherers of the region. In response to the ecological change, humans retreated to areas where wild grass was still available. In the vegetational refugia, humans adapted to the local ecology and exploited the food resources intensively. The chain reaction of events during that phase of a shift from mobility to sedentism illustrates that the impulse for that development was sparked by ecological changes that, in turn, induced responses of human intentionality to cope with those changes.

Sedentism is a stable feature in any agrarian society. For reaching the stage of full-fledged agriculture, sedentary populations in the ancient Near East experienced a step-by-step transition: sedentism of the Natufian people in the twelfth and eleventh millennia BCE (intensive exploitation of seeds of wild plants, beginnings of an intentional planting of wild seeds, no domesticated animals), sedentism of the early monument builders (at Göbekli Tepe and other sites) in the tenth and ninth millennia BCE (intensive exploitation of wild plants, intentional planting of wild seeds, no domesticated animals), and sequence of sedentism of the early inhabitants of Jericho (ca. 10,000–8500 BCE, sedentary hunter-gatherers; ca. 8500–7300 BCE, domesticated plants; ca. 7300–6000 BCE, domesticated animals [sheep and goats]). Thus, wild planting, plant domestication, and animal domestication are the major steps in the sequence from simple sedentism to full-fledged agriculture.

When we reconcile the insights that modern archaeology has provided about prehistoric belief systems with the history of human ecology, it suggests that the mobilization of humans for adopting a different lifeway had long-term con-

sequences for their worldview. In the societies of archaic hunter-gatherers, the division of labor produced gender-oriented specialization that can still be observed in traditional cultures. Men customarily go hunting and take care of the meat supply, while women provide food from gathering. It has been estimated that the supply of food from gathering made up 60 percent or more of the total diet in prehistoric hunter-gatherer communities.

If the major responsibility for gathering food lay with women, it seems reasonable to assert that women were the first to experiment with activities such as selecting and sowing the seeds of wild grass. Intensive gathering activity shifted to wild planting and ultimately to plant cultivation. The association of the sprouting of plants from the soil with the birth-giving of new life among humans would first originate in the minds of those who took the greatest burden of adaptation in the process of transition, that is, among women. Women were the ones to make the living space of early sedentary communities meaningful through their input of harvesting, storing, and baking activities.

The role of women for the progress of sedentism and for the conceptualizations of religious thought in early agrarian communities can hardly be overestimated. The female impact on the shaping of a new worldview is perhaps reflected in the ancient imagery. Typical figurines of the Early Neolithic Age (ninth and eighth millennia BCE) are those depicting standing or seated women. The seated woman type marks the canon of figurines throughout the Neolithic. This orientation toward the female gender may signal the increasing recognition of women in these societies.

Sedentary communities are more vulnerable to climatic fluctuations than are mobile bands of hunter-gatherers. Experience with the changes of the local weather and the dependence of cultivation on the conditions of the seasons for sowing and harvesting must have left permanent traces in the cultural memory of the early agrarians and led them to focus knowledge construction on insights about the eternal life cycle. Ideas about the organizing principles of wild nature extended into the new realm of plant cultivation. Here, human activities needed special protection to be successful.

There seems to be a growing consensus among paleoanthropologists, archaeologists, and scholars in the field of culture studies that the world of sedentary communities in the early Neolithic was as much spirited as the world of archaic hunter-gatherers, with the difference being that the worldview of agriculturalists is more complex and diversified. What makes a worldview spirited is that supernatural powers are made responsible for natural phenomena. An illustrative example of how very old beliefs in a spirited world can survive into our times is the traditions of animistic religions in a wide culturally interconnected zone in Asia, from northern Siberia to South East Asia. In Eurasian mythology, a female guardian-spirit resides in everything in nature, for example, in a tree, in a bird, or in a lake.

The difference with the transition to sedentism is that the lifeway of plant cultivators sets other priorities. While for hunter-gatherers, agriculturalists, and cattle growers alike, the rising and setting of the sun, the water supplied by rivers and lakes, and the fertility of animals is equally important, there are other phenomena that are of utmost importance for agrarian communities but a minor issue for hunter-gatherers.

This is true for rainfall, for the fertility of the arable soil, and for seasonal changes such as the fertility of the earth in spring and summer and the resting of nature in winter. Cults of rain gods are found in agrarian communities, not in the cultures of hunter-gatherers. Similarly, rituals focusing on the invocation of rain for the crops are typical for the religion of agriculturalists. So too are rites for the blessing of the fields and ceremonies of thanksgiving after harvesting.

Social patterns and the level of technological development in sedentary societies are more complex than in the communities of hunter-gatherers. This is also true for the level of specialization of agrarian rituals and ceremonies. The ritual calendar in agrarian communities requires more organizational infrastructure than the festivities of hunter-gatherers. The higher the degree of organization in this domain, the greater the demands for the professional specialization of the personnel responsible for ritual performance. Here opens the path for the trajectory toward the emergence of distinctly defined cults, the establishment of a seasonal ritual cal-

endar, the organization of cult personnel with permanent responsibilities, and the supervising role of a temple bureaucracy over the nature and amount of votive offerings and over the socioeconomic resources of the community.

In sum, the evolution of religious concepts among sedentary populations did not mean a rigid breaking away from the beliefs of archaic hunter-gatherers. Rather, what marks the difference is a gradual shift of conceptualizations about the life cycle toward new priorities of agrarian concern, while the close relationship between humans and their natural environment (i.e., wildlife) was not lost.

The Birth of the Gods? Natufian Religious Concepts

The massive melting of the ice sheets in the Northern Hemisphere that marked the end of the Ice Age was caused by global warming. This process continued until, in the course of the twelfth millennium BCE, another climatic change—with colder and drier weather—caused ecological changes in the vegetation of vast areas of the Near East. Wild emmer wheat and barley and almond and pistachio trees had provided a considerable amount of the food supply for mobile bands of hunter-gatherers that had

populated this region. When the soil dried out, these plants receded to isolated areas on higher grounds that were scattered, like oases amid dry land, throughout the region. The hunter-gatherers were forced to stay in the vicinity of these oases where there was enough water for plants, animals, and humans.

These conditions mark the transition to sedentism (remaining in one place rather than following a nomadic migratory pattern) in the Near East. One of the prominent cultures of this era is called the Natufian, which flourished throughout the Levant—though not in Mesopotamia—in the twelfth and eleventh millennia BCE. Sedentism effected a change in lifeways. Villages were formed, with circular houses in semisubterranean structures and storage pits (excavated at Kebara, el-Wad, Nahal Oren, Nahr el Homr, Dibsi Faraj, and Mureybet). The intense exploitation of the wild cereals in their refugia may have soon led to a shortage of the natural food supply and may have subsequently influenced the inhabitants of the villages to intentionally use the seeds for planting. This activity was a prestage of food production, but it was not yet practiced on a scale that later marked the beginnings of plant cultivation.

Those who experienced sedentism and engaged in the initial process of planting certainly became aware of the vulnerability of human ecology, with its fragile balance of food supply and water resources. The social bonds in the communities of the Natufian villagers extended to also include the ancestors who were buried in carefully designed cemeteries. Judging from the variety of artifacts that were found as grave goods, it can be concluded that the Natufians had a developed belief system with concepts about afterlife. The stone bowls in some graves may have served as cult vessels (e.g., for libation).

Among the tools that were found in the Natufian villages were bone sickles with stone implements, the typical tool for harvesting cereal grass. In addition, the Natufians produced mobiliary art. Small-scale pieces of art are rare before the Natufian period. The most prominent pieces from Natufian sites are bone artifacts, which were modeled and carved out with fig-

ural design. The motifs in these designs are stylized pictures of animal heads. Phallic objects are known from the el-Wad Cave near Haifa (Israel). An exceptional figurine was discovered at Ain Sakhri south of Bethlehem (Palestine). It depicts two persons engaging in sexual intercourse.

If one relates the pieces of mobiliary art, by their thematic nature, to the belief system of the Natufians, then it can only seem conclusive to see, in their art, reflections of an understanding of the process of procreation and fertility on the continuum of the natural world. The practical experience with the planting of the seeds of wild cereals and of the sprouting of new plants might have caused individuals to form an analogy with fertility among humans.

On the other hand, the evaluation of the information that we get from Natufian graves and the interpretation of Natufian imagery does not allow for statements about a putative pantheon of primeval gods and/or goddesses. The world of the Natufians was spirited, although they might have lacked clearly defined concepts of supernatural powers as personified figures, ascribing specific functions to individual divinities as did the agriculturalists of a later time.

The Natufians represent, with their subsistence economy of wild cereal planting, an early step to full-fledged plant cultivation. The beginnings of that phase in human socioeconomic evolution lie with the communities at Abu Hureyra in Syria and of Jericho (with evidence from the lowest strata) in the Jordan Valley around 8000 BCE. It is in the cultural milieu of those early agriculturalists, the successors of the Natufians, that concepts about divinities gain in profile.

Communal and Ritual Structures as Expressions of Religious Belief in the Ancient Near East

For a long time, it was believed that the world's oldest monumental structures were the megalithic temples from Malta, the alignments of menhirs (standing stones) at Carnac (Brittany, France), the stone circles of Stonehenge (Wessex, England), and the passage tomb of Newgrange (Ireland). Even the earliest dates for some of those monuments do not reach further back in time than the fifth millennium BCE.

Finds from newly discovered and excavated sites in the Near East have changed this picture. The beginnings of monumental architecture date to remote times in the tenth millennium BCE. This early age is itself a sensation. Also sen-

sational are the cultures in which the new finds are embedded. The early monumental structures were not erected by agriculturalists but rather by hunter-gatherers who had become sedentary. In this respect, the conditions of building activity in the ancient Near East differ from those in Europe, where the earliest monuments have to be attributed to members of agrarian communities. Another exceptional feature of this period of a dawn of monuments is that it precedes the technology of pottery making in the Near East and Europe.

The discoveries of early monumental architecture were made at a number of sites located in the Urfa Province of southeastern Turkey, and these are Nevalı Çori, Göbekli Tepe, Sefer Tepe, Hamzan Tepe, Karahan, Çayönü, and several others. Excavation activity at Çayönü started in 1964.

► THE EARLY TEMPLE AT ERIDU

The temple at Eridu housed one of the first religious cults in the world. There is evidence that the temple was rebuilt several times over a 3,000-year period (from 5400 to 2050 BCE), which may reflect its importance and significance to the people of Mesopotamia. Eridu is also believed to be one of the first cities, having been constructed around 5400 BCE astride the Euphrates River valley marshlands near the Persian Gulf. Archaeological evidence shows that the temple, or ziggurat, at Eridu was one of the first structures erected in the city. It was built in the city center in a depression that allowed for water to collect. The temple of Eridu was a mud-brick structure that housed an altar and offering table to the water god Enki (Ea in Sumerian), the patron deity of the city. Enki was credited by inhabitants of Mesopotamia as the creator of all humankind and was considered the perfect masculine type to which men should aspire. He was the god of fresh waters, intelligence, knowledge, and magic as well as the keeper of the Me, the gifts of civilized life. The cult of Enki controlled and oversaw tribute at the temple. Goods used for tribute included marine fish, ceramics, and other items. Aside from serving as a religious center, the temple of Eridu was also an important political and economic center.

Excavation at Göbekli Tepe in present-day Turkey. The site, believed by some to be the “first temple,” dates to the tenth millennium BCE. (Verity Cridland)

One of the sites, Nevalı Çori, was explored in a rescue excavation that started in 1983 and ended in 1991. Afterward, the area was flooded by the waters of the newly constructed Atatürk Dam that regulates the river Euphrates. Göbekli Tepe has been in the process of excavation since 1995.

All mentioned sites were inhabited by populations of hunter-gatherers. These had receded to areas where their major food supply—wild emmer wheat, barley, and some other food crops—was still available after the ecological changes that had been induced by the colder and drier climate in the course of the tenth millennium BCE. These people had become sedentary and had grown accustomed to an intensive exploitation of the local seeds of wild plants. Perhaps in those early sedentary communities planting wild seeds was already practiced to some extent; full-fledged agriculture was still in the future.

The monumental architecture that was erected by the hunter-gatherers was all communal buildings (called “cult buildings”) that served ceremonial and ritual purposes. The buildings at the various sites display typological similarities in their architectural properties, although their layouts differ locally.

The oldest cult building, at Nevalı Çori, was carved into the slope of a mountain to a depth of about 10 feet (3 meters) and had a size of some 46 feet (14 meters) x 44.3 feet (13.5 meters). The

inside of the rectangular building was structured by 15 stone pillars in a t-shape. Eleven of them interrupted a bench of quarry stone that runs around three sides. On the front side, there were two steps leading down to the interior. What makes this ceremonial hall unique is a podium in one spot of the bench. This space held the large sculpture of a bird.

On the foundations of this oldest construction, a new cult building was erected, with 11 pillars interrupting the bench and 2 in the center. The pillars in the center and some spots in the walls bear relief decoration. Among the major motifs are two human arms whose hands are joined, the carving of a snake in a niche, and reliefs depicting birds.

The sculptures that were found in the ceremonial precinct depict mythical beings. One is a female head on which a bird is perching, while another features two female figures, back-to-back, with a bird (perhaps a vulture) perching on them. There are some female figures whose bellies are swollen as if indicating pregnancy.

The Göbekli Tepe site shows semisubterranean monumental architecture. There are four circular structures that were partly cut into the limestone bedrock. These structures give the impression of crypts. Their interior is subdivided by pillars, two in the center and eight on the peripheries. The measures and weights of the central pillars are likely to emphasize the scale of these early monumental structures. The taller ones measure more than 6 feet (2 meters) and weigh more than six tons.

The pillars were decorated with pictures in bas-relief. The dominant motifs are wild animals such as snakes, birds, gazelles, lions, wild boars, and foxes. The images appear single or in groups. On some pillars, one finds complex groupings such as on the tallest pillar in the form of a stela (10 feet/3.1 meters), with bas-reliefs of a bull (above), a fox (middle), and a crane (below).

One of the images in the ceremonial buildings at Göbekli Tepe is mysterious since it differs from all other pictures in style and theme. This is the image of a mature woman with a round-shaped head who is in a squatting position with elongated labia and with her breasts hanging on both sides. The technique is canellure (or grooving) carving, and this stands

in contrast to the usual bas-relief technique. The figure is found on one of the bench lintels in the crypt that is called the Lion Pillar Building.

The cult buildings at Çayönü belong to the youngest phase of monumental structures in the area. They date to circa 8000 BCE, which is contemporaneous with the oldest occupation of an agrarian community at Jericho.

The largest of the cult buildings, a rectangular structure with an apse, is called the House of the Dead because 66 skulls were discovered beneath the floor together with skeletal remains of about 400 humans. In the center stands a stone slab, which has been interpreted as an altar. It might have functioned as a sacrificial stone, judging from the traces of animal blood. Since traces of human blood have also been found on the surface of the stone, it has been argued that this altar might have been the scene of human sacrifice. The validity of this conjecture, however, is still a matter of dispute.

The cult buildings stood as isolated structures. They were communal buildings, and their function was most probably that of ritual centers. The houses of those who constructed the communal buildings are located elsewhere, at some distance from the cult buildings. It has been estimated that many hundreds of people were engaged in the construction work, not including the workers who carved out the pillars from the bedrock. At Göbekli Tepe, the quarry was situated at some 295 feet (90 meters) from the nearest crypt. Sustaining such a workforce over weeks or possibly months required far-reaching planning, particularly with respect to the food supply.

There are many questions that cannot yet be answered. It is hard to imagine that the layouts for the cult buildings originated out of the blue, without prototypes or precursors. Where are these prototypes to be found? There is a hiatus in the cultural chronology between the era of the early monumental architecture and the tradition of ceremonial architecture of the times of the ancient civilizations in Mesopotamia. Where are the missing links? Was the belief system of the early sedentary hunter-gatherers the cradle of the religious cults of the later agrarian communities? Who were the heirs of their culture? Is there any direct line of descent leading from

the population that constructed the cult buildings to later populations of the Near East?

The Skull Cults in the Ancient Near East

The first information about an unusual burial custom in the Neolithic period came from Jericho, a site in the Jordan Valley excavated by Kathleen Kenyon. In 1953 she found three human skulls in a pit. Much about these skulls was exceptional, and the way they had been treated by the early inhabitants of the settlement was unknown to other regions.

The prominent features of these finds are that the skulls were separated from the skeletons and placed elsewhere; the surface of the skulls was covered with plaster; the interior of the skulls was filled with clay; the eyes were inlaid with cowry shells, transported some 31 miles (50 kilometers) from the coast of the Mediterranean; and all three skulls were positioned in a way that the eyes could “see” in the same direction.

Similar finds of severed and plastered skulls were made in different locations within settlements, such as Jericho, Kfar HaHoresh and Beisamoun in Palestine, and Ain Ghazal in Jordan. The postmortem removal of the skull is known from burial practices in the Near East. The beginnings of this custom can be dated to the tenth millennium BC, and it continued into the second half of the seventh millennium BC. The tradition of plastered skulls derived from the general custom of skull removal and was seemingly geographically restricted. Surprisingly, a plastered skull was found at Çatalhöyük in 2004, which means that the custom was evidently practiced also in Anatolia at an early stage of agrarian settlement.

Wherever they were found, the skulls were all intentionally positioned in groups. The spaces where the skulls had been collected made the impression of caches (skull nests). With more specimens of these plastered skulls found, other features of their treatment were revealed. One skull had brown paint on its top as if to indicate a headdress. Other skulls seemed to have worn masks, which were found next to them.

The special treatment of the head is also typical of statuary that is known from the site of 'Ain Ghazal. Big sculptures and busts of human figures, each measuring about 3.3 feet (1 meter) in height and made of clay, were retrieved from two caches. The statues in the one date to circa 6750 BCE, while those in the other date to circa 6570 BCE.

While the whole bodies of the older statues were modeled carefully, prominence in the younger ones lies with the heads. The contours of the eyes are marked with bitumen, and they have a staring gaze. All the sculptures were made in such a manner that they could stand upright in their specially dug pit.

Whether or not the “seeing” statues were associated with the “seeing” skulls is unclear, yet such exceptional finds spontaneously call for speculation about their symbolic meaning. From the beginning of the investigations, scholarly attention focused on the prominence of the eye zone with inlays. Obviously, “seeing” in the afterlife was considered by the Neolithic contemporaries to be an essential link for the deceased to be connected. The crucial question is, connected to what or to whom? In this scholarly opinions vary, although there is a general consensus that the special treatment of the eye zone was associated with a worldview that included concepts about a realm beyond the world of the living.

Once the focus is on the role of the inlaid eyes, there are several trajectories of interpretation: the “seeing” eyes may be a general metaphor for beliefs in a continuation of life after physical death; the “seeing” eyes may have specific symbolic meaning as an orientation for the deceased in the realm of the ancestors; the “seeing” eyes may symbolize an intentional preparation of the deceased individual for rebirth, such as an event in the process of regeneration; the “seeing” eyes

may symbolize the closeness of the deceased as a “living” ancestor and his or her continuing participation in the affairs of the living.

This last alternative interpretation is supported by the special conditions of skull nests under the floors of houses. Archaeologists refer to the plastered skulls and to their symbolic meaning as a religious pattern and prefer to call it cult. The skull cult is often—in a generalizing manner—described as expressing Neolithic people’s concern with death.

Circumstantial evidence, though, shows that the event of physical death was not the matter of main concern. Rather, it was the spiritual consequences of death and the perception of it as a stage in the eternal life cycle of birth, death, and regeneration that were of significance. In this view, the skull cults of the ancient Near East were not cults of the dead but rather ancestor cults, with stress on the spiritual linkage of the deceased with the memory of the living.

Goddess Cults in the Ancient Near East, Anatolia, and Southeastern Europe

There is a zone of ancient cultural convergence that stretches from the ancient Near East to Anatolia and beyond, including southeastern Europe. The origins of this convergence of cultural traditions and—most probably—also of similar worldviews date to a time prior to the birth of the Black Sea, that is, prior to the breaking of the land bridge that had connected Europe with Asia until about 6700 BCE. The land bridge had

facilitated the movement of people and the diffusion of ideas on both sides of the Aegean Sea.

Among the cultural markers of the convergence zone is a special category of artifacts that documents to the existence of ancient beliefs in female divinities, namely female figurines. Although the frequency of their occurrence varies in different periods, female figurines nevertheless constitute an element of cultural continuity and speak in favor of the sustainability of local societies over long spans of time. The cultural chronology of the figurines shows that by the seventh millennium BCE, this category of artifacts had spread over the whole convergence zone.

Different interpretations have been given for the role of female figurines in Neolithic societies, some drawing on the sacred and others on the mundane. The most conclusive of these approaches stresses the prominence of the female element in the belief system of people with an agrarian lifestyle whose world was filled with spirit entities. Before the emergence of the ancient civilizations of the Near East, there were no statues for gods and goddesses. Female figurines may have assumed symbolic meaning as metaphors of the divine feminine, as objects imbued with spiritual energy where the spirit of the divinity would crystallize. This can be inferred from the context of religious imagery and artifacts at the sites of ancient settlements (e.g., figurines in association with cult vessels in shrines, on cult platforms, or near the hearth or the baking oven).

The term “goddess cults” makes reference to certain religious practices (i.e., rituals, sacrifices, and votive offerings) related to the veneration of female deities. Although the concept of cult is widely used, it is but one aspect in the wholeness of a worldview that helped members of the agrarian community to perceive the role of the goddess as multifaceted, as the One and the Many. She was the Mistress of Nature, depicted in various forms of figurines (e.g., as wearing a mask resembling a bird’s head, appearing in the guise of a female bear nursing her cub); she was the patron of plant cultivation (the Grain Mother); and the guardian of the household, among other things.

The functional multiplicity of female deities that were venerated in the ancient convergence

Seated mother goddess figure, with exaggerated breasts, hips and belly. The right hand rests on the breast and the left on the hip. The flattened top of the head is a stylized depiction of a crown, a symbol of power. Anatolian, sixth millennium BCE. (Barbara Heller)

zone is reflected in the features of the goddesses of later times who can be identified by their names. There are the strong women of Sumerian mythology: Mami, the Great Mother Goddess; Tiamat, a primeval goddess; Ereshkigal, mistress of earth; Ishhara, goddess of marriage and childbirth; Zarpanitum, goddess of pregnancy; Uttu, the patron of weaving; Ninkasi, the patron of beer brewing; Ninurra, the patron of pottery making; and Nisaba, originally a grain goddess and later the patron of writing and knowledge. The Sumerian Inanna was a goddess of the Underworld. As Ishtar she gained in importance among the Akkadians and became the powerful goddess of love and war.

In the Near East, the attributes in the imagery of Ashera, the spouse of the god El, point in the direction of her role as the mistress of animals. From the pantheon of ancient Ugarit, the city-state that flourished from the fourteenth to the twelfth centuries BCE, Anat is known as the goddess of love, sister and consort of the mighty

➤ GODDESS WORSHIP AT ÇATALHÖYÜK (ÇATAL HÜYÜK)

Female figurines are among the cultural markers of community life in Çatalhöyük. The most famous of these is the sculpture of a mature woman sitting naked on a throne and flanked by leopards. This configuration of female figure and animals resembles similar sculptures from Hacilar (from the sixth millennium BCE) or from the sanctuaries of Cybele in Phrygian times (first millennium BCE). Çatalhöyük was founded in central Anatolia, in the plain of Konya, about 7400 BCE by sedentary people who practiced agriculture. This is the first urban agglomeration in the history of humankind that continued over a longer span of time. The main mound of the residential area at Çatalhöyük was abandoned around 6000 BCE, although human occupation continued nearby for some time beyond that date. Up to 8,000 inhabitants might have lived in the town at a time.

The ancient urban layout of the site was explored in the early excavations in the late 1950s and early 1960s, led by James Mellaart. He identified some of the courtyards between houses and the more spacious rooms in some of the buildings as sanctuaries and shrines of the goddess. The most famous of the sacred spaces is the hall with the figure of a female being in a squatting position, sculptured in bas-relief on the wall, in close association with bull's horns. According to Mellaart's interpretation, the female figure represents the Great Goddess of Anatolia whose

daughter, in later millennia, was Cybele. The Great Goddess of Çatalhöyük is referred to by the Turks as Ana Tanrıça (Mother Goddess).

This interpretation of the imagery at Çatalhöyük and the reconstruction of the large figure in bas-relief have not remained undisputed. Ian Hodder, who has led a new excavation campaign at Çatalhöyük since 1993, and his team acknowledge the presence of a powerful female divinity in the ancient community but recognize features of an animal, a bear, in the large figure of the sanctuary. They stress the close relationship of the inhabitants with wildlife and nature. Such a reconstruction, in fact, would not contradict the veneration of a female divinity in her role as the Mistress of Nature who appeared in the guise of the Bear Goddess, as in other communities of the convergence zone (see above). The same intimate relationship is suggested by a recently found seal, featuring a stylized bear, with a handle imitating the buttocks of a female body.

god Baal. The Phoenician goddess Ashtart (also known as Ashtort) later influenced the tradition of the Cyprian Aphrodite as the goddess of love and fertility. In Anatolia, the most powerful of the goddesses known by their names is Cybele, the motherly goddess, the protector of the community.

On the western fringe of the convergence zone, the pre-Indo-European heritage of the goddess cult is best known from ancient Crete with its Minoan civilization that flourished in the second millennium BCE. The opinions of scholars are divided over the fabric of Minoan religion. Some assume the presence of one mighty female divinity, while others reconstruct a pantheon of gods and goddesses. Even if Minoan religion

knew various divinities, the prominence of female deities among them remains striking.

The heritage of the strong women in pre-Greek mythology is reflected in the goddess cults of ancient Greece. All major achievements of Greek civilization are associated with goddesses: Demeter, the patron of agriculture (the Grain Mother); Hestia, the guardian of the hearth and the household; and Athena, the supergoddess, the patron of technologies such as pottery (the potter's icon was Athena's owl), shipbuilding, and weaving and the protectress of the community and the patron of justice, the arts, and science.

Of all the female deities once venerated in the ancient convergence zone, the goddesses of classical Greece—often in their Roman equiva-

lents (Demeter as Ceres, Athena as Minerva or Iustitia, Aphrodite as Venus, etc.)—live on in our cultural memory as elements of Western civilization, with many allusions to them in the visual arts and in literature.

Ancestor Worship in Ancient China

The tradition of ancestor worship (also referred to as ancestor cult) has deep roots in the cultures of East Asia, including China. It is from China, however, that the earliest evidence and the oldest documents have come down to us. The memory of the ancestors, either real or mythical, was ritualized and became the focus of social organization and political authority in ancient Chinese society. The identity of a lineage found its anchor in the ritual commemoration of the founding ancestor, and in the case of the lineage to which the emperor belonged, the founder of the dynasty had deified status.

Already in the earliest written documents from the end of the second millennium BCE, the oracle bone inscriptions, the basic unit of ancient Chinese society, the lineage (Chinese *tsu* or *zu*), is mentioned. The term *tsu* is rendered in writing as a complex ideogram, with the component of a

Shang dynasty tortoise shell with incised pictographs, from the archaeological site at Anyang. The Shang dynasty, which lasted from about 1760 to 1150 BCE, is the earliest Chinese dynasty supported by archaeological and documentary evidence. These inscriptions form the earliest body of Chinese writing, which can be traced back to 4000 or 5000 BCE. (Art Directors.co.uk/Ark Religion.com)

flag above and an arrow below. The flag was the iconic identifier of the *tsu*, and the arrow pointed at its function, which originally was that of a military unit of about 100 armed men, each from a household of the lineage. The head of the *tsu*, the lord, was the military leader during times of war. His role in community life was that of a guardian of social rules of behavior. There is consensus among Chinese legal historians that these rules had the value and weight of laws. The origins of the legal system in China have to be sought in this tradition of customary laws in the lineages.

The rule of behavior with absolute priority was the worship of the ancestors, the glorification of the founding ancestor in particular. When a lord engaged in building activity the

► THE EMERGENCE OF WRITING UNDER THE AUSPICES OF THE ANCESTOR CULT IN ANCIENT CHINA

The far-reaching impact of the ancestor cult on civic and military affairs in ancient Chinese society can be illustrated to the modern observer by means of the early written documents. The origins of writing in ancient China do not have to be sought in the context of bookkeeping, taxation, or incipient bureaucracy, as in the city-states of ancient Sumer in Mesopotamia. Rather, ancient Chinese writing was a medium of divination, and it remained so for more than half a millennium. Writing for the scope of divination on ritual bones was an innovation that was introduced around 1200 BCE.

Writing was a royal privilege and was used only by the emperor and his closest relatives. At the same time, writing played a key role for decision making. Before any significant event, whether civic or military, the emperor would consult with the ancestors. Questions such as “Is tomorrow an auspicious day for starting to build a new ancestral temple?” or “Will our army be victorious if we attack the enemy after the harvest season?” would be written—in logographic and ideographic characters—on the shells of turtles or on the shoulder bones of deer, which were then thrown into a ritual fire in the ancestral temple. A diviner (priest) would carefully supervise the action and later interpret the cracks that the fire produced on the bones. According to the interplay of cracks and signs of writing, the diviner would decode the advice and will of the ancestors.

Writing as a means of divination continued to be used into the times of the western Zhou. Later, writing lost its monopoly as a means in the religious context and was used as an information technology in profane functions.

—Harald Haarmann

ancestral temple had to be constructed first, and it was around this spiritual center that all major rituals and ceremonies in the community crystallized. When a lord neglected his duties to build an ancestral temple, keep it in good condition, or take care of the organization of obligatory rituals, he could be degraded by the emperor. Orders given by the lord to ordinary members of the lineage in connection with

these ancestral duties had to be obeyed. There were severe punishments for defiance of a lord that included mutilation and/or execution.

The highest authority in ancient Chinese society was the ruler (Chinese *wang*), the supreme head of all lineages. The origin of the Chinese character for writing the term *wang* is obscure. Some historians assume that it derived from the pictogram of an executioner's ax, thus referring to the absolute authority over life and death in the hands of the king (emperor).

Ancestors to whom the members of a lineage traced back their origins were not only worshipped as distant figures; their role for the living was more than that of a personified identifier of ethnicity. According to ancient beliefs, the highest wisdom of life lay with the ancestors. In practical terms, this meant that knowledge construction in ancient China was grounded in the appreciation and observance of the achievements of the ancestors, with the founding ancestor as the leading figure. Ancestors were invoked in prayers and rituals and were asked for advice.

A preferred means to consult with the ancestors was divination. The practice of divination by means of a bone ritual (*scapulomantia*) has a long tradition in China. Its origins date to the fifth millennium BCE. The diviners had a prominent status as officials of the Shang rulers. They were guardians of a secret information technology and of privileged knowledge.

In the early days, the diviners were often women. This is still recorded for the later period of the Shang and Yin dynasties (ca. sixteenth to eleventh centuries BCE). Under the rulers of the dynasty of the western Zhou (ca. eleventh century to 771 BCE), the authority of the office of the diviner shifted to male priests. Whether gender difference reflected preferences among individual members of the royal lineage or gender-oriented power relations in society is not known. The authority of female diviners in ancient China is no exceptional phenomenon when viewing divination in a comparative perspective of cultures in East Asia. Female shamans have had a prominent status among Siberian peoples. The privileged role of female diviners in society has been preserved, for instance, in Korean society up to the present. Korean women diviners are called *mu-dang* or *mansin* (ten thousand spirits).

The cult of the ancestors has never vanished from Chinese community life and has been perpetuated even through the communist era. April 5 is a day of ceremony for modern Chinese who remember their ancestors by performing memorial rituals in temples and praying to them. Ancestor worship has spread to neighboring regions, where Chinese influence was felt in historical times or is still vivid. This is true for Korea and Japan as well as for Vietnam in the south. On the day of Tet Nguyen Dan, the Tet Festival (New Year's Day), the ancestors are invited to participate in the celebrations in their honor, organized by the living. The beginning of the new year is marked as the first new moon in spring (ranging between mid-January and mid-February).

Religious Expression in Neolithic Europe

There has been much speculation about the belief systems among European populations during the Neolithic Age, that is, during the crucial period of socioeconomic transition from the communal life of hunter-gatherers to societies of agriculturalists. There are two major domains that provide information about religious expression in the Neolithic Age: (1) imagery (including

sculptures, reliefs, rock paintings, and engravings), artifacts, and structures related to cult practices (e.g., cult vessels, offering tables, altars, and holy precincts), and (2) narratives of mythopoetic contents that form part of the oral traditions of ancient and modern peoples. Written sources are not available from the Neolithic but instead date from the Chalcolithic Age (literally "copper-stone-age") in southeastern Europe (fifth millennium BCE, in an undeciphered script) and from the Bronze Age (end of the fourth millennium BCE in Mesopotamia).

The various theories about the spread of cult practices and related religious ideas distinguish themselves by their degree of association with conceptions about the social structures of early agrarian societies. Some see religious ideas among agriculturalists arising in a society with social stratification and with religious expression reflecting social hierarchy and power relations. Others recognize egalitarian social structures with women having a prominent (though not dominant) position in agrarian communities.

There is ample evidence from previous and recent findings among several disciplines (i.e., archaeology and comparative religion) to illustrate that most societies in the areas bordering the Black Sea in the south (southeastern Europe, Anatolia) were egalitarian. The abundance of female figurines that dominate the imagery in this zone of cultural convergence testifies to religious concepts focusing on female divinities as patrons of the abundance of the natural world that was of overall importance for the agriculturalists. This cycle includes the birth, growth, death, and regeneration of all living things.

In the communal life of the Neolithic people, an intimate interconnection between the cultural space that people established for themselves and their natural environment can be recognized. This close relationship can be seen as a heritage from earlier times, and comparisons are made between the older and younger periods of the Stone Age.

The cosmos that the Neolithic people constructed for their orientation was inhabited by mythical beings. One of the figures that illustrates the connections with the real world and the spiritual realm is the mythical bear that features in many pictures and sculptures of

Paleolithic art. This figure continues to appear in the Neolithic Age, sculpted as the natural animal or in hybrid figurines with female human features of the Bear Goddess.

Any comparison of the imagery and visual motifs of the Neolithic with those of the Paleolithic has to be approached with caution because the symbolic meaning of visually similar elements might have differed in cultures that were separated in space and time. And yet given the same kind of relationship between the cultural and natural space, the striking similarities in the canon of the imagery can hardly be overlooked.

The same holds true for certain types of narratives that recur in many oral traditions of contacting cultures. Myths are among the oldest themes of a mythopoetic interpretation of human beings' anthropocentric worldview, and similar motifs are found in many parts of Europe. Among the most archaic layers of narrative traditions are myths of origin that encapsulate tribally held ideas about creation, death, and the structure of the world. Different versions of the same archaic myth in different cultures may represent various developmental stages of the narrative repertoire. This is the case with the origin myth of the world egg, which forms part of the mythic repertoire of Uralic peoples in eastern Europe as well as the ancient Greeks and various peoples of the ancient Orient. The northern version contains more archaic features than the southern version.

In the myth of the world egg, two basic motifs are associated. One is the motif of the waterbird, the other that of a female guardian spirit or a goddess. The motif of the water fowl in various mythological associations is vivid in both narrative texts and visual representation. Saamic mythology abounds with narratives relating to the wild swan as a mythological animal. With good reason the Saami have been called the "people of the wild swan." According to Uralian mythology, a waterbird builds its nest on the knee of the Air Maiden (called Ilmatar in Finnish), who is reclining on the cosmic waters. Accidentally, the egg rolls into the sea and breaks, and from its contents the world finds its origins.

The North European version of the myth focuses on the totemistic aspect. The waterbird takes the active part in the creation process by

laying the egg, although the creation of the world may be understood as accidental, while in the Greek cosmogonical tradition the world originates from the creative spirit of a female deity whose creation is imbued with intentionality.

According to this version, the first divinity to emerge from the primordial chaos is Eurynome ("wide wandering"), the goddess of all things, whose first task is to divide heaven from the eternal waters. She cannot find a place to rest, so she wanders south on the waves. Eurynome is followed by the north wind, Boreas, who takes the form of a snake. His longing for a female companion culminates in a sexual union with the goddess, who becomes pregnant. Eurynome experiences a metamorphosis, turns into a water fowl, and places an egg on a patch of land. From this egg emerges all the things of this world, living and not living.

The mainstream Greek cosmogonical myths are collected in Hesiod's "Theogonia" ("Origins of the Gods") of the seventh century BCE, although there are other cosmogonies categorized as deviant by scholars, among them the so-called Pelasgian myth inherited from pre-Greek times. In this version, the central position of the goddess as creatrix of the world is indicative of the pre-Greek origin of the cosmogonic myth.

The formative period of the mythical narrative of the world egg may well date to pre-Neolithic times. This variant of a myth of origin continued into the Neolithic and beyond, such as in the case of Greek mythology, and in northern Europe it has even survived up to the present.

Also on European soil, another tradition of religious expression—deviant from the canon in the egalitarian agrarian communities—originated during the Neolithic Age. This was the pantheon of predominantly male divinities that is typical of the cosmos of the proto-Indo-Europeans with their socially stratified society and their pastoralist economy, which had originated in the steppes of southern Russia. The early imagery focuses on the horse as a mythical animal. Later, with the Indo-European migrations, the model of a male-dominated pantheon and of a hierarchically structured society, with political power concentrating in the hands of a social elite, was to be transferred into other parts of Europe.

Chinchorro Mummies

Dating to between 5050 and 1100 BCE, the Chinchorro mummies are the world's oldest anthropogenic, or artificially created, mummies. These mummies were originally discovered on the Chilean coast near the modern-day city of Arica by archaeologist Max Uhle. He named the mummies Chinchorro, meaning "fishing net," based on the elaborate fishing technologies interred in their burials. Subsequent excavations, however, have shown that these mummies existed along the coasts of Peru and Chile spanning from Ilo, Peru, to Antofagasta, Chile. The term "Chinchorro" is also used to refer to the culture with which these mummies are associated. The Chinchorro people were a preceramic culture that specialized in marine subsistence strategies and complex mortuary traditions.

Chinchorro mummification practices began in the Camarones Valley in northern Chile and are believed to have spread to other regions. Men, women, and children were all mummified. Studies have led researchers to conclude that mummification was open to all members of the group regardless of age, gender, or social status, with mummification styles varying by time. Based on evidence of their repair, the mummies may have been used in ritual ceremonies and were eventually buried in group burials along beach sites.

There are several different types of mummies associated with the Chinchorro culture, including Natural, Black, Red, Bandaged, and Mud-coated mummies. These mummification

Mummified Chinchorro baby, San Miguel Museum in Arica, Chile. (Ivan Alvarado/Reuters/Corbis)

types were created at specific times over the 4,000 years the Chinchorro employed their anthropogenic mummification practices. The extremely arid conditions of the region often created naturally mummified human remains.

Black-style mummies are the oldest and most complex mummies and date to between 5050 and 3000 BCE. Their creation entailed the removal of the skin of the deceased followed by the removal of all of the remaining soft tissues. Organic materials were then used to re-create the shape of the individual, with the body being reinforced and secured with wooden poles and reed cords. The skin was placed overtop the organic materials, and the face and sex organs were remodeled with clay. A short black wig

made of human hair was placed on the deceased's head, and the body was painted with black-blue manganese paint.

Red mummies were less complex than the Black mummies and occurred between 2500 and 2000 BCE. The soft tissues of the deceased were removed through slits cut at strategic points on the body, such as along the shoulders and groin. The head was removed, and the body was dried by placing burning materials into the body cavity. The body was reinforced with sticks and stuffed with organic materials, the incisions were stitched, and the head was reattached. The head was then adorned with a long black wig, and the body was painted with red ochre.

Bandaged mummies were created in a similar fashion to the Red mummies and date from 2000 to 1100 BCE. The main difference between these two types of mummies is that the Bandaged type is wrapped with long pieces of animal or human skin.

Mud-coated mummies were the simplest and were created by drying the body without removing the internal organs. The body was covered with a thick mud paste after it was placed in the burial.

It is unclear as to why the Chinchorro began to mummify their dead, but three hypotheses concerning their origins exist: adoration of children, ecological factors, and spiritual con-

cerns. The adoration of children hypothesis asserts that the Chinchorro may have begun mummification on children first as a way of assuaging community grief, later incorporating adults as their belief system developed. The ecological factors hypothesis states that through observing the natural mummification processes, the Chinchorro felt the need to perfect the process based on a need or desire to control the environment. The spiritual concerns hypothesis centers on the idea that mortuary rituals, such as mummification, enabled and guaranteed reincarnation as well as allowed the living to communicate with the deceased in the afterlife. Nonetheless, scholars believe that no single hypothesis can explain the origins of the Chinchorro mummification practices.

Science and Technology

If nothing else, our species has a remarkable capacity for invention. Although other animals, including ants, otters, and birds, are known to make tools, the tools made by these species and the contexts of their use are ephemeral and highly situational. Among our nearest primate relatives, chimpanzees are known to make simple tools and have even been seen modifying stones in a way that must have been very similar to the ways in which the australopithecines knapped stone almost two million years ago. But chimpanzees show little capacity for creating new forms of tools or using them habitually. Our evolutionary lineage is the only one to have engaged in consistent technological innovation. Our capacity to learn was bolstered by our growing ability for learning and the transmission of knowledge through social learning from one generation to the next.

The pace of technological change, however, was slow for the first one million years or so. Most of the stone tools that our early ancestors made were probably for a single episode of use, and their forms changed little over long periods of time. Even the beautiful and symmetrical Acheulian hand axes persisted in a recognizable form over hundreds of thousands of years and over large geographic areas. This suggests that these tool forms were well suited to the tasks for which they were created and that the environmental and behavioral contexts within which they were used changed slowly as well.

A serious problem in the study of early technological innovation is the loss of tools made of perishable materials such as wood, fibers, or other plant materials. It is likely that many of the stone tools we find in the archaeological record were used to shape and fashion these tools. And like our chimpanzee relatives, our ancestors may well have used unmodified sticks, branches, and similar objects to obtain their food. Thus, while we have good evidence for stone tool manufacture as early as 2.5 million years ago, it is highly probable that some of our ancestors, notably *Australopithecus afarensis* and *A. africanus*, used tools of perishable materials.

Technology is not just about objects but is also about the contexts and behaviors associated with their use. One of the great controversies about the evolution of our species is whether our early ancestors were primarily hunters of animals or scavengers of the carcasses of animals killed by disease, old age, or predators. Hunting involves behaviors that are distinct

Thus, while we have good evidence for stone tool manufacture as early as 2.5 million years ago, it is highly probable that some of our ancestors, notably Australopithecus afarensis and A. africanus, used tools of perishable materials.

from those of scavengers. Stone tools can contribute little to this debate because they could have been used to both kill and/or butcher the animal carcass. To resolve this debate, it is necessary to look at the species processed, their size and age distribution, and the contexts of their discovery. Hunters may show preference for certain types of animals, whereas scavengers may not be so selective. Whatever the outcome of this debate, it provides an important reminder that technology is not just about things but, more importantly, is about how things fit into the subsistence systems and social lives of the people who used them.

Technological change is in great part driven by adaptation. Technologies, broadly defined, are modified as circumstances demand. New tools are created, production processes are refined or redefined, and new uses for old tool forms may be developed. “Necessity is the mother of invention” is true to a point, but it is also true that technological change is not always driven by need. People often modify their technologies to take advantage of new opportunities. The process of domestication of plants is a good example of this. In some parts of the world, foraging peoples were attracted to large stands of wild plants that appeared as climate improved at the start of the Holocene not out of necessity but because they offered an opportunity to obtain resources with greater security. Stone tool technologies were subsequently modified to harvest these stands of plants more efficiently.

Structures and shelters are a somewhat different kind of technology. When did our ancestors begin to create them? Our primate relatives live and sleep in the open, sheltered by trees or vegetation, and it is likely that our most distant ancestors did likewise. Although circles of stone are said to exist at Olduvai Gorge that some have described as remnants of a structure, others have disputed this claim. Somewhat later in time, we have good evidence that our ancestors used rockshelters as a kind of natural structure and may also have lived in the light zones of caves. Structures made by our ancestors, however, appear in a number of regions during the Upper Paleolithic. In part, this may reflect the movement of our species into colder regions where protection from the elements was a necessity.

With the advent of sedentism, the pace of technological change increased dramatically. This was due in part to the significant increase in population in these areas as well as greater demands for subsistence technologies to feed more people. New technologies, such as ceramic manufacture and metallurgy, appeared. Increased levels of regional interaction through trade and exchange created new markets for specialist production of commodities such as salt, obsidian, and textiles. Elite demand for exotic or luxury items spurred technological innovation as well. By the end of the era, thousands of new technologies had been invented, reinvented, and borrowed.

We owe this tremendous capacity for innovation to our ability to observe within the context of our evolving capacity for symbolic representation and thought. Symbols allow us to envision new things and then to put those objects to use. Observation is the close study of the natural world. Together, symbols and observation have made us what we are today. Our power to observe and then reason is a kind of presci-

entific mind-set. That is, while it is very unlikely that our ancestors framed their observations in the modern language of science and hypothesis testing, it is also clear that they put things together in novel ways and conducted natural experiments with them. People who know nothing about genes, for example, are quite aware of the potentialities of cross-breeding plants and animals to improve their yields. And while most of their innovations were supremely practical, this does not disqualify them as a kind of prescientific thinking.

The contributions to this theme explore our evolved capacity for innovation over a two million-year span and attempt to place them into a wider social, political, and economic context.

—Mark Aldenderfer

■ Introduction: Tools and Technologies of the Early and Middle Paleolithic, 2.5 Million–100,000 Years Ago

Aside from the fossil remains of our earliest ancestors, stone tools perhaps provide the most critical insights into the evolution of our species. Simply put, stone tools are durable records of behavior and are certainly the most ubiquitous remains of the earliest stages of our evolution. Although it is likely that our most distant ancestors used tools fashioned from wood, bone, leaves, and even grasses, these perishable materials are seldom preserved from deep antiquity. Our early past may not be written in stone, but it is in great part reflected by it.

Making a stone tool requires some manual dexterity. Although our closest primate relatives, especially chimpanzees, have been known to make very simple stone tools, their hands are not suited for making and using tools in an efficient manner. The development of an opposable thumb—a digit when, combined with the others, creates a powerful grip that is simultaneously precise in movement—was one of the key steps in providing our ancestors with the dexterity to use tools of all kinds effectively and habitually.

Stone tools also reflect to some degree the cognitive abilities of our ancestors. Even the simplest tool requires some foresight and a sense of possible outcomes. All early stone tools were created by striking one stone with a harder stone, and not just any stone is suitable for making a tool. Over time, our ancestors learned

which kinds of stone could be struck that would lead to the desired outcome. As tools become more complex, then, they reflect the growing cognitive abilities of our ancestors.

Although our ancestors may have used unmodified rocks and stones to crush bones or mash plants, we cannot easily see these activities in the archaeological record. The earliest stone tools that we know of are called unifacial tools and are modified on only one side, or face. Many of these early tools were little more than sharp edges that were presumably used to cut meat from bones or process plants. The first stone tool tradition, that is, tools that were made and used consistently in a region over a specific period of time, is known as the Olduwan and is found in eastern and southern Africa. The first Olduwan tools date to approximately 2.5 million years ago and persist until around 1.5 million years ago.

Around 1.6 million years ago a new tool tradition, the Acheulean, emerges from East Africa. This tradition, best characterized by large bifacially worked hand axes, was remarkably persistent and successful and in its most basic form lasted until 250,000 years ago and spanned three continents. This was the tool industry carried by *Homo ergaster* as that species moved out of Africa around one million years ago. Unlike unifacial tools, bifaces require more skill and planning to produce, and this suggests that the cognitive

capacity of *H. ergaster* was superior to that of the australopithecines or early *Homo*. In addition to hand axes, the Acheulean is characterized by a wider diversity of unifacial tool forms, suggesting their use in more complex tasks.

The earliest Acheulean hand axes, those dating before 600,000 years ago, were relatively crude. While worked bifacially, they lacked real symmetry, were relatively thick, and in some cases cortex, which is the exterior surface of the stone used to make the tool, was left on the hand ax. In contrast, the hand axes of the Late Acheulean were highly symmetrical, very thin, and very carefully made. Some archaeologists have argued that the appearance of these finely made tools implies a significant advance in the cognitive capacity of the individuals who made them and thus may reflect the appearance of *H. heidelbergensis*, who is likely to have been the first of our ancestors to occupy the European continent.

The Acheulean, however, is not found in East Asia, and here the tool industries contemporary with it are known as a chopper/chopping tool complex with varied regional names. The species most closely associated with these tools is *Homo erectus*. Although the tool forms in East Asia are relatively simple when compared to those of the Acheulean, they nevertheless were a key aspect of the successful adaptation of *H. erectus* in the varied environments of East Asia.

Although our ancestors undoubtedly used a wide range of natural materials in their daily lives, it is only after 500,000 years ago that we begin to see the first vestiges of tools made of other materials. Bone is well known to be an important source of tools for modern peoples, and large bones can be flaked and worked much like stone. Large hand ax-like tools made of bone are found in Europe at this time, as are other crude bone flakes and chopping tools. Likewise, wooden tools have been found, again in Europe. The Theime (or Schoeningen) spears, most probably used in a thrusting manner, date to around 400,000 years ago. Evidence for other technologies, such as fire and the creation of structures, begins to be found in the archaeological record at this time but is still very rare. Evidence for clothing, basketry, and textile making are unknown for most of the Paleolithic, although it is probable that *H. heidelbergensis* made crude

clothing, given the harsh environment of Europe that species encountered when it migrated into the continent.

With the disappearance of the Acheulean tradition around 250,000 years ago, the number of distinctive tool traditions seen in the archaeological record increases substantially. In part, this reflects the appearance of species transitional to *H. sapiens* in Africa as well as the growth of numbers of our ancestors living in distinctive environments that led to the development of tool traditions more suited to these local settings. In Africa, the period from roughly 250,000–100,000 years ago is known as the Middle Stone Age. In Europe and southwestern Asia, the Mousterian is the name of the tool tradition during this period and tends to be associated with *H. neanderthalensis*. In general, stone tool technologies at this time reflect a growing trend of specialization of function and a progressive decrease in size. Many of the tools of these varied regional traditions are well made and show careful attention to symmetry and design, a pattern that clearly indicates the presence of a high level of cognitive capacity.

Toolmaking by Our Closest Primate Relatives

Tool use and toolmaking is widely considered an important aspect in the evolution of the human lineage. Generally, human cultures are defined by the tools they use: of what material they are made, how they were made, and what use they possibly could have had. Humans are, however, by no means the only toolmaking primates. Monkeys and apes share this ability, each on its own level. The chimpanzee and the orangutan are the most creative in toolmaking, while gorillas miss this ability altogether.

A tool can be any object from the environment that is used to perform a task; even parts of one's body can be considered a tool in the broadest sense. Tools fall under two different categories. The naturefacts are tools in their unchanged original state. The artifacts are based on objects that are deliberately changed to improve their usefulness. Under the first category fall the leaves that are used by chimpanzees to collect water or to wipe themselves clean and the sticks to reach an object. Toolmaking can be applied only to the second category. Artifacts are thus objects that are modified to make it a tool.

Toolmaking by primates was not discovered until October 1960 when Jane Goodall observed that chimpanzees in the wild in Tanzania make and use tools. This was a shock for the scientific community, which until then had made a neat distinction between the toolmaking humans and the nontoolmaking apes. The reaction of Louis Leakey on the report of Jane was, "Now we must redefine tool, redefine Man, or accept chimpanzees as humans."

Jane Goodall observed that chimpanzees use sticks to extract termites from their hills. The chimpanzees deliberately modify twigs and grasses into suitable tools by stripping them of their leaves. The self-made stick is then carefully inserted into a termite hill. The agitated insects will attack the stick, and once enough attackers are attached to it, the chimpanzee slowly withdraws it and eats the termites. Young chimpanzees learn the technique by imitating adults, though it takes them years to become successful termite fishers. The use of the sticks is not limited to termite and ant fishing but also includes collecting honey from beehives and digging up edible roots. The stripping of leaves from a twig can be considered the very beginning of toolmaking. Somewhat more sophisticated is the joining of two sticks together to make a longer tool for reaching high places. Chimpanzees in captivity have been observed to do so.

Stone artifacts or stone tools were long considered unique to human cultures. A trained chimpanzee named Kanzi, however, learned how to knap stones simply by watching people do it. No attempt whatsoever was made to help him position his hand correctly or make use of the proper arm motion. Chimpanzees in the

wild occasionally use stone flakes in order to obtain meat from bones. These primitive stone flakes differ little from the stone artifacts attributed to early humans. Such observations dim the difference between apes and humans, earlier defined as "Man the Tool Maker."

Different chimpanzee groups use tools in different ways, thus constituting different chimpanzee cultures. There is, however, no evidence of different toolmaking, analogous to human cultures, between the groups.

Among the apes, only gorillas seem not to be able or willing to make tools. They do use sticks as the other primates do and also use various types of containers to store water. Deliberate modification of these objects to improve its use is, however, not observed. Orangutans, on the other hand, have also been known to braid twigs into ropes to facilitate climbing. As with chimpanzees, orangutans remove inefficient aspects of naturefacts and so make it an artifact.

As compiled by Benjamin Beck, monkeys too have been known to utilize tools in many ways, but in almost all cases this concerns naturefacts, not self-made artifacts. A rare exception is formed by captive hooded monkeys that were observed while making spoons from pieces of wood to extract yogurt from narrow tubes.

Apart from primates, birds especially prove to be excellent toolmakers, such as the woodpecker finch of the Galapagos Islands, which uses a cactus spine to spear insects. This finch deliberately shortens too-long cactus spines in order to form more manageable tools. In this way it transforms a natural object into an artifact.

Stone Tools

Stone tools (also referred to as lithics) are artifacts created through a process called flint knapping. Flint knapping involves striking a stone with another object in order to remove flakes

A comparison of stone tool types found throughout the prehistoric record. Spearheads and arrowheads would have been hafted onto wooden implements and were not invented until 50,000 years ago. (Illustration by Jeff Dixon)

from it. The stone from which the flakes are removed is called the core. The striking object is classified as either a hard hammer or a soft hammer. Hard hammers are normally stones that are harder than the core, while soft hammers are often made from bone or antler. The waste flakes resulting from lithic manufacture are classified as debitage. The product is the tool.

There are three main techniques used to remove flakes from the core. The most basic method, called direct percussion, is to hit the hammer directly against the core. Indirect percussion involves placing a punch between the core and the hammer. When the punch is hit, the knapper is able to achieve greater flake removal precision. The third method is pressure flaking, which is used to modify a flake knapped off the core. In most cases a piece of antler or

bone is used to remove tiny flakes along the edge of the flake to shape, dull, or sharpen it. This is achieved by firmly pressing the soft hammer directly against the edge of the flake. These flint-knapping techniques can be used independently or in combination.

The Paleolithic (Old Stone Age) dates from approximately 2.5 million years ago, when stone tools first appear in Africa, to 10,000 years ago. Over these 2.5 million years, stone tools evolved as knapping techniques evolved and skill improved. As a result, archaeologists subdivide the Paleolithic into three periods. The Lower Paleolithic, dating from 2.5 million to 250,000 years ago, is predominantly made up of larger and more primitive stone tools. Generally, the core is shaped into a single tool that is used for a number of activities. There is little variability in the tool assemblages. Around 250,000 years ago the knapping technique changed significantly. Instead of shaping the core into a single tool, the core was knapped to produce usable flakes, which were then modified into tools using the pressure flaking technique. This change in knapping technology allowed the knapper to create several stone tools from one core. These flake tools dominate the Middle Paleolithic period. During this period more tool types were created, although many still seem to have been used for multiple purposes. The Upper Paleolithic, beginning around 40,000 years ago, is marked by a shift to blade tools, although flake tools continued to be manufactured. A blade is defined as a flake with a length that is at least twice as long as the width. Blades were produced from a core using the indirect percussion technique. These lithics are much more refined. Many different types of tools were created, some of which had a specific purpose.

Plant domestication and the creation of ceramics around 10,000 years ago in the Near East mark the end of the Paleolithic and the beginning of the Neolithic (New Stone Age), although stone tools continue to be made up to the present day.

Olduwan Tools

The oldest stone tools found thus far come from the site of Kada Gona, Hadar, Ethiopia, and date to circa 2.6 million years ago. Several other sites in East Africa including Olduvai Gorge, for which these early artifacts are named, have also yielded stone tools. These tools have been found at sites that date back to the Lower Paleolithic period, between 2.6 million and 1.7 million years ago. The stone tools found at the various sites over the million-year time span are remarkably similar. They are grouped together as belonging to Olduwan Industry.

Olduwan tools are generally crude in form. Most are made using the hard-hammer direct-percussion technique. Locally available stone (the core) was hit with a hammerstone to remove flakes. These flakes were occasionally modified along an edge to create a scraper or were used to cut without any modification, but the more common Olduwan tools are cores from which flakes (debitage) have been removed. Based on the shape and size and the knapping technique used, Mary Leakey typologically classified the core tools found at Olduvai Gorge into different tool types. Her classification system remains widely used.

Choppers are the most basic Olduwan tool. They are created by striking off a few flakes from one end of the core to create a sharp edge. When only one side of the end is knapped, it is a unifacial chopper. If flakes are removed from both sides so that the knapped edge intersects, it becomes a bifacial chopper. Cores with more extensive flake removal are classified as discoids, spheroids, or polyhedrons based on their final shape (that being disk, sphere, or cube-shaped, respectively). However, their final shape may have more to do with the initial core shape than the knapper's vision. Eventually, the stone tools become more refined, and protobifaces begin to appear, but true bifaces, which are cores extensively knapped on both surfaces, do not appear until 1.7 million years ago.

As noted by Haviland, the appearance of Olduwan tools marks a significant technological

WHO MADE OLDUWAN TOOLS?

Between 2.6 million and 1.7 million years ago when Olduwan tools were made, there were at least three different hominids living in Africa. *Paranthropus* (or *Australopithecus*) *boisei*, *P. robustus*, and *Homo habilis* remains have been found at several sites. This situation is further complicated, as many of the sites with Olduwan artifacts are either not accompanied by skeletal remains or have bones from two different species, as is the case at the FLK Zinj site at Olduvai Gorge. Based on skeletal morphology, the robust *Paranthropus* species could have made the Olduwan tools; however, most scholars agree that it was the gracile *Homo habilis* (meaning "handy man" for this toolmaking ability) that produced them. Their main argument is based on the evolution of Olduwan into Acheulean tools, which were made by *H. habilis*'s successor *Homo ergaster* (African *Homo erectus*). Furthermore, Lower Paleolithic tools continued to be crafted long after the *Paranthropus* species died out.

advance for the hominids. These tools allowed them to process their food more effectively and enabled them to incorporate new foods into their diet. Why the Olduwan tools appear is unclear, but climate change may have played an important role. Between three million and two million years ago the climate in Africa became drier. As a result, forests shrank, and grasslands increased. The hominids may have been forced to turn to other food resources in order to survive, therefore needing tools to access them. Whatever the reason, the manufacturing of Olduwan stone tools contributed to the evolution of modern humans.

Acheulean Tools

Around 1.6 million years ago the Acheulean industry developed out of the preceding Olduvan industry. These new Lower Paleolithic artifacts include more sophisticated stone tools. They are associated with *Homo ergaster* (African *Homo erectus*), who evolved from *Homo habilis* at this time. Although Acheulean tools first appear exclusively in Africa, they eventually spread into

Asia and Europe as the hominids migrated to these regions. In fact, the industry was first identified at the site of St. Acheul, in France. Lasting until at least 200,000 years ago in some areas, the Acheulean industry is the longest-lasting, most widespread lithic tradition.

The Acheulean industry includes a number of skillfully made bifacial (knapped on both surfaces) artifacts, the most famous of which is the hand axe. This teardrop-shaped tool is pointed at one end and rounded at the other. It was likely manufactured using the soft-hammer direct-percussion technique, as is the case with many of the Acheulean tools. Using a soft rather than hard hammer facilitates more precise flake removal from the core, therefore allowing the knapper to create a more symmetric tool with thinner edges.

➤ MOVIOUS LINE

The areas occupied by hominids during the Lower Paleolithic are determined mainly by the location of where stone tools are found, although fossil remains add to this assessment. By 500,000 years ago, Africa, southern Europe, and southern Asia were populated. It is assumed that the hominids traveled out of Africa into these new areas, bringing their Acheulean tool industry with them. Interestingly, however, not all sites yield Acheulean tools. In Southeast Asia, for example, the Chopper Chopping-tool industry is present. Traditional hand ax tools are also missing in the northern reaches of the newly occupied areas outside Africa. Hallam Movius was the first to note this phenomenon. The defined boundary separating the different tool traditions is now commonly referred to as the Movius Line. Since his publication, however, several sites were discovered that bring the boundary into question. However, most archaeologists agree that there remains a geographic division between the lithic industries.

➤ KOOBI FORA

Koobi Fora is located on the east side of Lake Turkana in Kenya. Discovered by Richard Leakey in 1948, it continues to be one of the richest Lower Paleolithic sites in the world. The incredible succession of deposits, dating between about 4.3 million and 0.7 million years ago, has yielded a rich sequence of fossils and artifacts. Hundreds of skeletal remains of *Australopithecus anamensis* (ca. 3.9 million years ago), *A. africanus* (ca. 2 million–1.7 million years ago), *Paranthropus boisei* (ca. 2 million–1.4 million years ago), *Homo habilis* and/or *H. rudolfensis* (ca. 2 million years ago), and *H. ergaster* (ca. 1.7 million–1.3 million years ago) have all been found. The oldest tools discovered, dating between circa 2 million and 1.8 million years ago, consist of choppers and flakes. They are classified as the KBS industry (falling within the Olduvian industry). These tools precede the Karari industry (Developed Olduvian), which includes choppers, discoids, polyhedrons, and a few protobifaces, dating to 1.4 million years ago. The beautifully crafted Acheulean tools evolved directly from these Olduvian objects.

An Acheulean pick is similar to a hand ax in size but is trihedral (three-sided) rather than bifacial. It is a bulkier, cruder artifact that is not as symmetrical as a hand ax. Cleavers have a sharp flat edge instead of the pointed end of hand axes and picks but remain rounded at the base. The flat end is often wider than the base but is much thinner. Choppers, discoids, spheroids, polyhedrons, and retouched flakes, similar to those associated with the Olduvian industry, are also found in Acheulean assemblages.

Acheulean tools are more standardized than those of the Olduvian industry, implying that they were intentionally designed by the flint knapper. Moreover, the different tool types may have been crafted to serve different purposes, although this is very difficult to prove due to the lack of preservation. Based on the large numbers of broken bone at many Acheulean sites, it is clear that the occupants were butchering animals for consumption. Stone tools would have been necessary to perform this activity. Cleavers

may have been used to butcher the animals, and retouched flakes may have been used to cut the meat. Lithics would have been employed to process plants as well. Hand axes and picks could have served to dig up roots, although they were likely used for other purposes as well.

The advance of lithic technology seen in the Acheulean industry may have been the prerequisite that enabled *Homo ergaster* to move out of the forest onto the open savanna and into the regions outside Africa. Eventually the ability to control fire, to hunt rather than scavenge, and to construct shelters, among other skills, were achieved.

Asian Stone Tools

Based on the recent discovery of skeletal remains at Dmanisi, Georgia, in Southwest Asia, the first exodus of *Homo* out of Africa took place around 1.7 million years ago. The hominids traveled through Northeast Africa into Southwest Asia. Although dating slightly later, artifacts are found at a number of sites in this newly inhabited region, confirming the migration. Some of the hominids continued eastward, eventually reaching present-day China and Java. Due to the fact that the climate and environment in Southeast Asia were different than in Africa, the hominids adapted, eventually evolving into Asian *Homo erectus*.

Artifacts assumingly manufactured by *Homo erectus* differ from those of the Acheulean industry in Africa, Europe, and Southwest Asia. True hand axes and well-made bifacial tools are absent in Southeast Asia. Instead, choppers and flake tools, along with large numbers of flakes, make up the assemblages. They are grouped together as the Chopper-chopping tool industry. In this industry choppers are defined as cores with flakes removed from one end on one side (unifacial choppers), while the chopping tools have flakes removed from both sides (bifacial choppers). Flake tools are created by either purposely pressure flaking the edge of a flake in order to shape, dull, or sharpen it or through use. When a flake is used to cut, saw, or scrape, small flakes break off of the working edge. In either case, these flake tools are technically classified as retouched flakes.

The oldest confirmed Chopper-chopping tool industry artifacts in Asia come from the Nihewan Basin in China and date to about 1.66 million years ago. Other similarly early artifacts, dating to approximately 800,000 years ago, were found near Ban Mae Tha in northern Thailand and at Trinil in central Java. The best-known Chopper-chopping tool assemblage comes from Zhoukoudian Locality 1, near Beijing. More than 100,000 artifacts were discovered at this site, which was occupied numerous times between

750,000 and 25,000 years ago. Most of the artifacts found are flakes, with very few choppers or retouched flakes present. The characteristic tool is a quartzite unifacial chopper. Several *Homo erectus* remains were also found at Locality 1, confirming the link between the hominid and the tools.

During the period that *Homo erectus* occupied Southeast Asia there was very little change in the lithic technology they employed. The variability that does exist is likely due to the nature of the local stone used to create the tools and flakes. It is not until the arrival of *Homo sapiens* around 50,000 years ago that new artifacts are seen in this region.

Perishable Tools from the Lower Paleolithic

Stone tools make up the majority of the Lower Paleolithic artifacts due to their durability. However, perishable tools were likely important to the hominids as well. Perishable tools are made out of bone, wood, reeds, hide, skin, or other soft material. In extremely arid, waterlogged, and cold environments, perishable tools can survive, providing a more complete view of the different artifacts used by early humans.

Animal bones found at sites in Africa, Europe, and Asia occasionally have percussion marks on them, suggesting that they were used as soft hammers or for pressure flaking. Careful study of lithic artifacts has confirmed the use of bone and antler tools in the flint-knapping process, even at sites lacking preserved animal bone.

➤ OSTEODONTOKERATIC TOOLS

Osteodontokeratic tools are those made of bone, teeth, and horn. This term was first used by Raymond Dart to classify the bone remains at Makapansgat, South Africa. Dart believed that the australopithecines found at the cave site made tools out of animals they hunted. He noted the broken animal bones had rounded edges, smoothed and polished surfaces, spiral fracturing, and damaged ends, which he believed to be the result of hominid processing. His findings are no longer accepted by most archaeologists. The broken bones at Makapansgat and other early Lower Paleolithic sites are now most often viewed as the result of carnivore activity or natural weathering. Furthermore, as Brain concludes, the

australopithecine remains found at Makapansgat were actually brought in by carnivores, such as lions and hyenas, along with the other animal bones. In other words, they were the prey, not the hunters. There is no evidence that the australopithecines made either bone or stone tools.

—Shawn Bubel

At the Acheulean sites of Fontana Ranuccio, Magliocchia, and Castel di Guido in Italy, elephant bone artifacts were discovered. These artifacts were knapped on both sides to create bifacial tools. Scraperlike artifacts, also made of elephant bone, were found at the non-Acheulean site of Bilzingsleben, Germany. These bifaces and scrapers were knapped the same way one would make a stone tool, implying no change in technology but an expansion of raw material use.

A few wooden artifacts have also been found, although it is debatable whether some are true artifacts or the result of natural formation processes. A piece of willow wood shaped and polished through use came from Gesher Benot Ya'aqov, Israel. This piece and others from the 780,000-year-old site may be the oldest perishable tools discovered. A possible hunting spear point came from Clacton-on-Sea, England, although others argue that it is an ice probe, a digging stick, or a stake. At the site of Kalambo Falls in Zambia, Clark interpreted several finds to be shaped wooden artifacts, one of which may be a club. The most remarkable wooden artifacts come from Schoeningen, Germany. At this 400,000-year-old site, three carefully designed wooden spears were found along with a double-pointed wooden stick and three wooden branches that may have been used as handles for stone tools.

➤ THIEME SPEARS

Archaeological investigations led by Hartmut Thieme at the Schoeningen coal mine site in northern Germany uncovered three wooden spears in 1995. They were remarkably well preserved in a deposit of organic mud together with butchered animal bones and lithic artifacts. The spears, each made out of a separate spruce sapling, range in length from 5.9 to 7.5 feet (1.8 to 2.3 meters). They were all manufactured the same way. The harder and denser wood at the base of the tree was sharpened to create a point, while the opposite end tapers gently. Remarkably, each spear was weighted like a modern javelin, with the balance point situated at about one-third its length from the point. Based on the morphology of the spears, Thieme interprets these to be projectile weapons rather than thrusting spears. If this is the case, these approximately 400,000-year-old wooden artifacts may be the oldest throwing spears ever discovered.

—Shawn Bubel

Bibliography

- Thieme, H. "Lower Palaeolithic Hunting Spears from Germany." *Nature* 385 (February 27, 1997): 807–810.

Besides the bone and wooden artifacts, no other Lower Paleolithic perishable tools have been found. Nevertheless, Pope believes that bamboo was used by *Homo erectus* to create efficient, durable, and easily portable tools. Bamboo artifacts would have complemented the lithic tools of the chopping tool industry of Asia. According to Pope, the effectiveness of bamboo artifacts may explain why the East Asian stone tools seem of lesser quality when compared to the contemporary Acheulean industry. Until bamboo tools are discovered, however, their use remains difficult to prove. Similarly, reed and leather tools may have been created by the hominids living in Africa, Europe, and Asia but are missing from the archaeological record.

Structures

An archaeological structure is a nonportable object, such as a wall, floor, or shelter, constructed through human (or hominid) intention. Based on the seemingly patterned arrangements of stones, early structures have been proposed at a handful of Lower Paleolithic sites, the oldest of which is the 1.75 million-year-old site of Dk1 at Olduvai in northern Tanzania. The discovered circular feature of basalt rocks was initially interpreted as a structure, but subsequent investigations have shown it to be the result of tree root growth. Natural processes have also been identified as the agents that created the 450,000–380,000-year-old stone arrangements at Terra Amata in southern

France. This also seems to be the case for Soleilhac, in southeastern France. Roebroeks and Kolf-schoten (1994) interpret not only the 65-foot (20-meter) line of basalt rocks but also the suggested pre-Acheulean artifacts to be of natural origin.

Concentrations of artifacts and bones may mark the presence of huts or similar structures at Bilzingsleben and Ariendorf 1 in Germany and Le Lazaret in France. At the 350,000-year-old site of Bilzingsleben, three circular to oval ring patterns of large stones and bones have been explained as weights to secure tentlike structures. These features were complemented with hearths and activity areas in front of them. Excavations at Ariendorf 1, dating between 301,000 and 242,000 years ago, revealed several large stones, partly surrounded by bones and artifacts, that may belong to the base of a structure. The fact that the quartzite stones and archaeological remains were found within a sandy-silt deposit suggests cultural placement. At the 186,000–127,000-year-old cave site of Le Lazaret the concentration of artifacts and bones seems to have been bounded by a line of large rocks running parallel to the cave wall. Lumley and Bonne believe that these rocks may have served as supports for tent poles. Although compelling, none of the cases have been confirmed.

Unequivocal evidence of structures prior to the advent of modern humans 50,000 years ago is limited, and no definite structures are seen prior to 130,000 years ago. Archaeologists agree, however, that structures of some sort would have been essential for those living in the cooler regions of Eurasia and were probably used in other regions as well. The lack of conclusive evidence may be due to the fact that many of the early structures were likely constructed with organic materials that rarely preserve over time. Furthermore, most structures would have been temporary, used only for a short time as the people moved across the landscape. Therefore, they would have been quickly constructed with little or no intention of perpetuation.

Caves, Rockshelters, and Open-air Sites

The archaeological sites of our earliest ancestors fall into three types: caves, rockshelters, and open-air sites. Each has produced important evidence for the evolution of our species and the technologies they employed. Caves are generally described as subterranean passages that have three distinct elements: a light zone, where natural sunlight illuminates the entrance to the cave; an intermediate zone, where natural light penetrates but does not brightly illuminate the interior of the cave; and a dark zone, in which no natural light of any kind can be seen. There is a common belief that most of our ancestors were “cavemen” and lived in the deep interiors of caves, but this is a misconception. Although some of our ancestors, notably *Homo neanderthalensis* as well as our own species, used the light zones of caves for habitations, none ever used the dark zones of these spaces as habitations. However, there is ample evidence from the Upper Paleolithic of western Europe that dark zones were used for ritual purposes. Examples of caves used in this manner include Lascaux, Altamira, and Chauvet Cave.

Occasionally, however, remains of our ancestors are found deep in the dark zones of caves.

DK 1

The Lower Paleolithic site of DK1 (Douglas Korongo) in Olduvai Gorge, Tanzania, dates to approximately 1.75 million years ago. Excavations lead by Mary Leakey in 1962 uncovered Olduvai artifacts, including choppers, polyhedrons, discoids, spheroids and scrapers, fragmented animal bones, and a partial *Homo habilis* skull. Associated with these remains was a circular concentration, 13–16 feet (4–5 meters) in diameter, of loosely piled basalt rocks on the same surface upon which the artifacts were found. Most of the rocks measured 4–10 inches (10–25 centimeters) long. The maximum height of the stone concentration was 11.8 inches (30 centimeters). The area immediately outside the stone circle, within a radius of about 20 inches (50 centimeters), was relatively void of stones. Leakey suggests that this feature was either the remnants of a stone windbreak or the base of a rough shelter. If this is the case, it may be the oldest structure in the world. Conversely, Potts argues that the circular feature was created naturally. He proposes that lateral tree roots growing into the lava deposit directly below the site broke it apart and brought the basalt rocks to the surface. Even if Potts is correct, there is no doubt that *Homo habilis* manufactured stone tools at DK1.

Examples include Swartkrans in southern Africa and Sima de los Huesos in Atapuerca, Spain. At Swartkrans, the remains of australopithecines found in the caves appear to have been deposited by predators who consumed their prey while resting in trees above the entrance to the cave. The bones, some of which exhibited tooth marks, fell into the entrance, which later collapsed. At Sima de los Huesos, however, the remains of a Neanderthal-like species appear to

➤ LE LAZARET

Le Lazaret cave is located in southern France. It was occupied sometime between 186,000 and 127,000 years ago. The spatial location of the Acheulean archaeological remains suggests the construction of a structure inside the cave. Lithic artifacts and fragmented animal bones were found concentrated between the cave wall and a line of large rocks in an area approximately 36 by 11 feet (11 by 3.5 meters). The excavators speculate that the rock line supported poles used to pitch a tent against the cave wall. Possible entrances are marked by two breaks in the rock line, where artifacts flow out of the structure. Two circular charcoal pockets, thought to be hearths, were located near the cave wall. Interestingly, a large number of small seashells were also found, which may have been attached to seaweed brought into the cave for bedding. Substantive evidence confirming the presence of a human-constructed shelter at Le Lazaret is absent, however.

Excavation at Le Lazaret cave in southern France. (Marc Charuel/Sygma/Corbis)

have been intentionally deposited into the cave system essentially intact. This may represent a form of early mortuary, or burial practice, but since almost no other material aside from bones has been recovered from the cave, it is difficult to make this assertion.

Rockshelters are natural features that exhibit overhangs that protect inhabitants from wind, rain, snowfall, or other elements. Rockshelters do not have dark zones. In the modern era, hunters and gatherers use these overhangs for temporary camping stops or as habitations and occupied them for relatively long periods of time. These kinds of uses can also be seen deep in our prehistory.

Open-air sites are found in many different kinds of places upon the landscape. The simplest of these may be sites where someone had stopped to knap flint to make a stone tool. Here, the remains left behind would be very sparse. Some open-air sites are long-term habitations and contain the remains of structures and other features built by our ancestors. Depending on how long or how many times the sites were occupied, these sites can accumulate large amounts of artifacts.

Because they are relatively easy to locate, caves and rockshelters have been worked extensively by archaeologists seeking to obtain data about our deep past. In contrast, open-air sites

of early time periods are very difficult to locate because in many cases, they have been buried or destroyed by natural processes. However, to get a complete picture of the lifeways of our ancient ancestors, it is important to make an effort to discover sites of all three types, because each provides a slightly different picture of how people used the landscape in the past.

Fire

The ability to control fire is a milestone in human evolution. Where and when this was achieved is intensely debated, however. Many archaeologists suggest that fire was first controlled in Africa and that it is this skill that allowed the hominids to travel out of Africa into Asia and Europe. Others believe that fire was controlled long after the migration to regions outside Africa. Resolving this issue is complicated due to lack of preservation and the difficulty of distinguishing a natural fire from a cultural one.

Evidence for the earliest human-made fire may come from the sites of Koobi Fora and Chesowanja in Kenya. Baked clay deposits dating to 1.5–1.4 million years ago suggest purposely lit fires, although Isaac argues that naturally ignited smoldering vegetation could have produced the same results. Pieces of burned bone were found in cave deposits dating between 1.4 million and 1.0 million years ago at Swartkrans, South Africa. According to Brain and Sillen, the 270 charred bone fragments denote controlled fire use. Their experiments demonstrated that the bones were heated beyond what a natural fire would produce, but other scholars remain unconvinced. Similar disagreements relating to the dispersed ash found at the Cave of Hearths and Montagu Cave in South Africa persist.

Lower Paleolithic sites outside Africa are marked with the same problems. Dispersed char-

coal was found at Torralba and Ambrona, Spain, as well as at Prezletice in the Czech Republic, but there is no way to prove human involvement. Alternatively, the circular feature of fire-cracked basalt rocks at the 700,000-year-old site of Kao Poh Nam, Thailand, could be the oldest campfire, but this discovery awaits authentication. What seems to be the oldest confirmed evidence of culturally made fire comes from Locality 1 at Zhoukoudian, China. Thick ash deposits, ash lenses, burned stones and bones, and charcoal pieces dating to as old as 600,000 years ago were found at the site. Although the thicker ash beds and some of the burned remains may have been deposited in the cave by natural processes, the ash lenses seem to attest to human activity. However, it is not until the Middle Paleolithic period (beginning around 250,000 years ago) that unequivocal evidence of human-made hearths is seen.

Regardless of when humans learned to control fire, they probably first obtained it from sources that were already burning, such as brush fires, volcanic eruptions, and oil and gas seepages. Early humans may have camped near or used the natural resource to scare off predators or warm themselves. Once they learned how to harness fire, they were able to use it at distant open-air and cave sites, especially those that required protection from predators.

Seeing Evidence of Fire in Deep Antiquity

When our ancestors began to control and use fire in their daily lives is a contentious issue in the discipline of archaeology. Fires, of course, can be created by natural events such as lightning strikes, and so it is crucial to define what kinds of evidence are unequivocal indicators of hominin or human activity. Ideally, the best evidence would be from hearths, or intentional facilities created by our ancestors to contain the fire. Burned or charred bone, burned artifacts, remains of wood ash, soil discolorations resulting from heating, and combinations of these found in a small, apparently bounded, space would be most convincing. Such features become very common after 130,000 years ago and thus indicate that *Homo sapiens sapiens* had full control of fire. But are there any earlier sites?

Because of problems of archaeological site preservation, the data on the deep antiquity of

the use of fire is very scarce. Sites like caves or rockshelters, for example, are likely to preserve evidence of fire better than open-air sites. The two early sites that have the best, if still controversial, evidence for the controlled use of fire are Gesher Benot Ya'aqov in Israel, dated to approximately 800,000 years ago, and Zhoukoutien in China, which is dated to between 670,000 and 400,000 years ago. At Gesher Benot Ya'aqov, small concentrations of burned lithic debris are surrounded by scatters of unburned artifacts and animal bones. These concentrations may be hearths in the sense described above. At Zhoukoutien, thin strata of burned soils that contain charred and burned bones suggest hearths as well. Both of these sites fall within the time frame of *Homo erectus*, and fossil remains of this species have been recovered from Zhoukoutien.

Understanding when our ancestors began to use and control fire has a number of important implications for the history of our species. Fire

➤ ZHOUKOUTIAN

Zhoukoudian (Locality 1) is a cave site situated 30 miles (45 kilometers) southwest of Beijing. Excavations began in 1927, and since then remains of more than 40 *Homo erectus* individuals and roughly 100,000 artifacts belonging to the Chopper-chopping tool industry have been discovered. In addition, thick ash beds, ash lenses, burned stones and bones, and charcoal pieces were found throughout the 131 feet (40 meters) of deposits. Tattersall and Schwartz note that the thicker ash beds and some of the burned remains may have been deposited by natural processes, but most archaeologists are convinced that the ash lenses attest to learned fire technology. Based on recent dates acquired, the site was occupied for 350,000 years, between about 600,000 and 250,000 years ago. If *Homo erectus* is responsible for the ash lenses, Locality 1 may be the earliest site in the world with culturally made campfires.

would have made it possible for our ancestors to use the coldest environments on the planet. The absence of sites in much of the higher latitudes of the Northern Hemisphere before 400,000 years ago suggests that the controlled use of fire was not widespread before that. Fire is also important because cooking makes all foods more digestible. The common use of fire after 130,000 years ago may be a signal of one

aspect of behavioral modernity in our species, one that may have given those groups who controlled it effectively a competitive edge over those who did not.

■ Introduction: The Tools and Technologies of Early Modern Humans, 100,000–10,000 Years Ago

With the appearance of anatomically modern humans after 100,000 years ago, stone tool technologies underwent a series of dramatic changes when contrasted to earlier periods of human evolution. For the preceding two million years, the pace of technological change was relatively slow, and new technologies and tool forms appeared fairly gradually. In contrast, after 100,000 years ago the pace of change in the range of flint knapping (stone toolmaking) technologies and the numbers of tool forms themselves intensified. These changes can be attributed to a number of factors, the most prominent of which was the expansion of niches occupied by our species. After 60,000 years ago, our ancestors began to move for the second time out of Africa and into a series of highly diverse ecological niches, including deserts, high plateaus, the subarctic, and tropical forests. Although the characteristics of an ecological niche do not in themselves determine the specific stone tool reduction strategies or the forms that tools take, it is clear that different niches created new constraints and opportunities for our ancestors regarding their subsistence adaptations and also that changes in stone tool technologies were an integral aspect of the process of adaptation to them.

The term “Upper Paleolithic” is often used to describe the stone tool technologies of this period, and historically it has been generally applied to technologies found in Europe and the Near East. This generic term is replaced with

more regional and local terms as the number of dated tool assemblages from excavated archaeological contexts increases.

Although different niches led to the development of distinctive local technologies and tool forms, four general trends that crosscut these niches can be observed: the appearance of sophisticated bifacial reduction strategies, blade-core technologies, more special-purpose tools, and a wide range of composite tools.

Although bifacial technologies can be found as early as the Acheulean tradition, after 100,000 years ago bifacial tool reduction strategies became more sophisticated. Bifacial strategies conserve raw material because more finished forms can be made for a given quantity of raw material. Bifacial tools are those that are worked on two faces, and the most common of the tool forms produced by this technology are projectile points of different shapes and sizes, depending on the task for which they are intended. Tool functions served well by bifacial implements also include cutting and slicing soft materials (“knives” with thin sharp edges) and sawing or whittling wood, bone, or antler (tools with thicker edges).

Blade-core technologies create prismatic blades, which are long, thin, and narrow flakes. This reduction strategy conserves even more raw material than a bifacial strategy. Blades can be easily transformed into a wide variety of useful tools, including burins, scrapers, awls, and knives.

Throughout this period, the number of tool forms increases dramatically. New technologies

make this possible, but the appearance of such diversity in tool forms also means that our ancestors were using them for a wider range of activities. Ethnography informs us that tools become more specialized in their forms as they are turned to very specific tasks.

A good example of this is the set of tools used for hide working. Our ancestors used animal hides for shelter and also for clothing of different styles and qualities. To make simple cloaks of hide, it is only necessary to remove the fatty tissue on the inside of the hide to make it usable. Relatively large crude scraping tools are sufficient for this task. However, as clothing becomes more complex and requires more steps for its production, more tool forms are required. Although the larger tools may still be used for the initial steps of hide preparation, smaller tools with specific forms, perhaps hafted, may be used for finer work in which more control is required.

Another set of tool forms that appears during this period is that used to work bone, antler, and wood. Although it is likely that more distant ancestors used stone to work these materials, apparently these activities did not require special tool morphologies. In the Upper Paleolithic, special tool forms to work these materials become more common. Tools such as burins, easily made from prismatic blades, are used to score and groove bone or antler so that it can be carved or split more easily. The end products of bone working were tools such as barbed projectile points, bone or antler hafts, harpoons, and needles.

Composite tools are those made of more than one raw material. The simplest composite tool is a spear made of wood tipped with a stone or bone point. This kind of composite tool was probably made by *Homo neanderthalensis*. However, during the Upper Paleolithic, the range of composite tools increased dramatically. Many of these tools were used for hunting. For instance, wooden spear shafts were edged with small broken segments of prismatic blades (bladelets). This created a weapon that would tear flesh more effectively than a spear tipped with a stone point. One important innovation in hunting tools was to create so-called foreshafts, which were smaller bone or antler tools that were placed on the end of wooden spears. The stone tip would then be placed in the foreshaft.

Archaeologists believe that foreshafts were created to preserve the most expensive part of the hunting equipment, which was the wooden shaft of the spear itself. Small, more specialized stone tools were used to make these foreshafts.

At the end of the Upper Paleolithic, primarily in the Near East, a new stone tool reduction strategy emerges, one based upon the creation of small blades, or microliths. The term “Epipaleolithic” is used to describe the cultures making these tools. Microblades are intentionally made very small blades that are used in composite tools similar to those made with snapped bladelets made during the Upper Paleolithic. Some archaeologists have argued that microlithic tools were used to make complex hunting weapons that were used to hunt a wider variety of animals, including smaller species that were ignored in previous periods. This change in stone tool technology and hunting strategy is coincident with increased reliance upon wild plants and increasing sedentism. Microlithic technologies became much more common across much of the Old World as deglaciation progressed.

Hands, Minds, and Tools

The ability to use tools is not restricted to humans. Chimpanzees in West Africa use sticks to batter the shells of nuts to crack them open. What distinguishes the use of tools among humans from the realm of other living creatures is the diversity and sophistication of tools for general and specialized use that humans have designed in the course of cultural history. The ability to use tools reaches beyond our species (i.e., *Homo sapiens sapiens*, or modern humans) into the remote past and includes various earlier hominins, the first being *Homo habilis*.

The earliest tools that were made of stone appear some 2.6 million years ago, found at sites in Ethiopia (Hadar and Gona regions) and Kenya (shore of Lake Turkana). According to their

mode of production and criteria of their specialization, stone tools are categorized into five modes: Mode 1 (simple chopping tools), Mode 2 (bifacially flaked tools), Mode 3 (standardized and retouched flakes), Mode 4 (narrow stone blades), and Mode 5 (microliths, or small delicate artifacts). With increasing complexity of the industries to produce the desired shape or type of an instrument, the human mind is challenged to apply innovative technologies. The thrust of innovation is spurred by the demands for functional specialization of the tools. The innovations of Modes 4 and 5 are associated with modern humans in the Eurasian context.

The finds of long spears near Schoeningen (northern Germany), dating to some 330,000 years BP, is evidence for the skills of *Homo erectus* who roamed the region before the Ice Age. Various abilities have to be activated to guarantee a successful production and use of a spear, including the choice of a suitable material for reuse that would not break after the first throw, the hardening of the tip in fire, learning how to balance the weapon, and practicing the coordination of body movement and the interplay of fingers and thumb. In order to hunt with a spear the hunter has to learn how to track down animals and how to approach them within the range of the weapon. The hunters who used the spears—the oldest known in the world—in the remote past killed wild horses, which is evidenced by the bone remains in the campsite.

The technical skills of Neanderthals were more advanced. This species devised a remarkable improvement in the fabrication of a spear, namely incising the tip and inserting a sharp stone implement. Spears, clubs, and hand axes were used by hunters in the Upper Paleolithic. The invention of bow and arrow appeared much later in the arsenal of weapons designed by modern humans. The pictures in cave and rock art of Africa and Eurasia that depict humans with spears belong to an older period than those that feature hunters with bows and arrows. Although a spear is a tool that is far too complex in its design and function to be used by chimpanzees, this instrument is much less complex than the ensemble of bow and arrow.

The question arises as to how an elder hunter would have instructed a member of the

THE MIDDLE STONE AGE OF AFRICA

Until recently, it was believed that behaviorally modern humans first emerged in the Upper Paleolithic of western Europe around 50,000 years ago. New evidence from Africa, however, challenges that belief, and stone tools play a significant role in that challenge. The discovery across the continent of a wide variety of complex tool forms suggests that their makers had created composite tools forms—likely made of stone and wood—much earlier than had been previously assumed. In Africa, the Middle Stone Age is dated between roughly 190,000 and 50,000 years ago. Stone points from Howieson's Poort in southern Africa, dated between 70,000 and 60,000 years ago, may have been used as tips on wooden spears. Small geometric-shaped microliths have been discovered at the site of Mumba in Tanzania and are dated to 65,000 years ago. Typically, microliths are used to create a sharp serrated edge along a wooden shaft. They are embedded into the wood, thus creating a powerful thrusting spear that does more damage to the animal into which they are thrust than spears with simple sharp points. More complex tool forms suggest changes in hunting strategies or species targeted. These tool forms, together with other kinds of evidence such as decorative art, extensive use of red ochre in nonfunctional settings, and more complex settlement patterns, all point to a wider behavioral repertory in these late Middle Stone Age peoples.

younger generation to build and use a bow. Was it necessary to use language for instruction, or could the training be carried out through productive action and visualization of techniques? There are those who think that the unfolding of language was stimulated by instructive needs to transmit technical knowledge from one generation to the next. Others believe that the process of language skills was independent from such demands. Instruction with or without language

is not a matter of opposite alternatives but rather is one of choice on demand. There are certain phases in the process of technical instruction that work without language, while others require verbal explanation.

Since the time of *Homo erectus*, who appeared some 1.6 million years ago, the brain of hominins has been equipped with the neurological infrastructure for symbolic activity. Language is a sign system whereby individual verbal signs have arbitrary symbolic meaning. Capacities involving symbol making and abstract thinking alike are required for the manufacturing of complex tools as well as for the use of language. In all probability, the skills of tool industry interacted vividly with linguistic skills. All in all, the use of verbal signs in connection with activities to manufacture and apply tools was just one trajectory among others to enhance the evolution from protolanguage to complex language.

There is a special facet in the relationship between manual and mental activities, involving language, and this is the specialization of language usage in association with the division of labor. The assumption has been made that specialized tools such as stone scrapers (to clean animal skin) or bone needles (to tie pieces of skin with fibers for clothing) were used by women and also manufactured by women. So, a mother would have instructed her daughter to produce certain tools and how to use them. In a similar way, a father would have instructed his son to make and use a hunting weapon. The distinction between women's language and the terminology of men's occupations, which is first documented in Sumerian texts of the third millennium BCE, may find its origin in remote prehistoric traditions.

Mousterian Lithic Industry

The Mousterian lithic industry from Middle Paleolithic times was very systematically executed by its manufacturers. This industry dates from circa 120,000 to 40,000 BCE. This technology for making chipped stone artifacts flourished in western and central Eurasia, South Asia, the Middle East, and Africa during most of that time span.

The different artifact combinations of 55 different tool forms seem to be functional tool sets, although some geographic variation has been observed. The Middle Eastern Mousterian is nearly always derived from specially prepared cores known as the Levalloisian technique, but in Europe and central Asia additional ways served to prepare cores for deriving flakes. In North Africa, the Aterian variant exhibits a hafting tang, while the Pontic in central Italy consists of small artifacts. The southwestern French and northern Spanish variant is distinguished by extremely skilled and systematic tool manufacture.

The Mousterian represents the tool inventory of Neanderthal humans (*Homo neanderthalensis*) in Europe, central Asia, and parts of the Middle East, but the makers of the Mousterian are not so well known in Africa and South Asia.

Besides flaked stone tools of flint there are a small number of ground stone artifacts such as abraders, polishers, and hammerstones. Except for hammerstones, such tools are very rare. Art-

work consists of a few beads of bone and shell. In the European Balkans, some fine points were used to make flutes from cave bear foot bones.

These final Mousterian Audi assemblages are the only assemblage combinations with a chronological implication. All the other Mousterian assemblages date from circa 120,000 to 75,000 BCE, the time of the last interglacial and the onset of the final glaciation, the Wurm in Europe. All the other four kinds of assemblages are made up of various combinations of the same 54 or similar kinds of tools.

The basic tool combinations form the sets Typical Mousterian, Mousterian of Acheulean Tradition, Set A and Set B, La Quina, Ferrassian, and Denticulate Mousterian. In general, all the combinations could be made with either of the two basic flaking techniques. The Levalloisian or prepared core technique produces thinner flakes than the discoidal core technique so that the Ferrassian is very similar to the more massive La Quina assemblage made from discoidal cores, but the Ferrassian has the thinner flakes. The Levalloisian struck flakes always have tiny flake scars formed by the preparation of the point of impact for the hammerstones that removed the flakes.

The Typical Mousterian is the most generalized of all the Mousterian assemblages and can be made with either the Levalloisian prepared core technique or the discoidal core. This assemblage has a rather full range of tool types, which includes sidescrapers and endscrapers, and is the one with the most Mousterian triangular points. This category includes a number of different tools in themselves, some being knives and others perforators, and a few of the thinner ones may even be projectile points. Typical assemblages are the ones that accompany mammoth kill sites in Europe.

The Mousterian of Acheulean Tradition, Set A, includes bifacial tools sometimes called hand axes. These are much smaller and thinner than the older Acheulean true hand axes, forming flat equilateral triangles. The use of these implements is unknown. Knives seem a bit more common in this kind of Mousterian assemblage also, and these assemblages are always found in the early last glaciation before the Main Würm Interstadial Complex.

A later Mousterian with hand axes is called Set B or Audi Mousterian, but here the hand axes are rarer, smaller, but less carefully flaked and triangular than those of Set A. These tools are joined by a kind of backed knife with a straight cutting edge and a semicircular back that is blunted so that the pressure of a finger can be exerted against it in use. The knives are called Audi Points. The Set B assemblage occurs at the top of Mousterian stratigraphy as a late Mousterian.

The La Quina Mousterian consists primarily of large and thick ovate sidescrapers, which seem to be used in the first stages of mammal hide preparation. In western Europe, where children are the only deceased to receive grave goods, these are La Quina-type sidescrapers. These are always made with the discoidal core technique and may make up nearly 60 percent of the tools found.

The Ferrassian is very similar to La Quina except that the thinner sidescrapers are made on flakes produced on Levalloisian cores.

The Denticulate Mousterian is another specialized kind of assemblage, being made up of predominantly small flake tools with irregular serrations along the cutting edge. These may make up over 60 percent of the tools in a Denticulate Mousterian. It is postulated that these are cutting tools for plants, but at Chassemy in northern Champagne, France, they occur at an open creekside site and fireplace where freshwater shellfish were opened.

These Mousterian lithic combinations are puzzling but do convey an idea of the mental sophistication and manual dexterity of the Neanderthals who made them. The amount of planning required for the preparation of the cores to make flakes is impressive, and when cutting implements are desired, a flake is produced that requires minimal subsequent retouch to shape it.

The European and Southwestern Asian Upper Paleolithic

Developments in Europe and Southwest Asia (Near East) during the Upper Paleolithic, a period lasting broadly from 40,000 to 10,000 years ago, in terms of early human activities allows for the examination of technological changes by archaeologists that allowed for particular lifeways in the increasing complexity of human societies. Moreover, this is the period when early humans (*Homo sapiens sapiens*) replaced Neanderthals in Europe. Early human societies formed during this period adopted lithic assemblages composed of blades and intricate composite tools and also developed cultural manifestations in cave art and other forms of material culture. Questions over the interactions of early humans and Neanderthals and what ultimately became of Neanderthal society are still being considered by archaeologists based on the evidence available from this period of history. The Upper Paleolithic encompassed revolutionary changes in human culture and society, shaping the understanding of how anthropologists conceive of the beginnings of the behaviors and cognitive abilities of modern man through the study of technological changes that occurred during this period.

Long-term developments during the Upper Paleolithic in early human societies, based on archaeological evidence, suggest significant changes from the prior Middle Paleolithic period in terms of cultural, material, and behavioral manifestations. Population increases and the development of exchange networks between Upper Paleolithic societies indicate the establishment of trade as a viable economic function between hunter-gatherer bands. Such early human societal lifeways have allowed archaeologists to decipher the shift from the mainly pastoral, isolated nature that characterized much of Middle Paleolithic hominid societies to that of more sophisticated Upper Paleolithic early human hunter-gatherers. Much of the archaeological evidence for this process has come from Europe and Asia. While such exchange networks were within a few hundred kilometers at most, they do suggest the development of societal interaction for the purpose of trade and an understanding of the value of items by humans.

Upper Paleolithic assemblages illustrate the development of the systematic manufacturing of blades and their further production into microlithic stone tools. Upper Paleolithic tool manufacturing, in its Aurignacian and Mousterian forms (also used by Neanderthals), indicates the level of sophistication in tools as early humans adopted increasingly complex production methods and far more intricate composite tools composed of items other than stone. Other raw materials, such as bone, antler, and wood, were also used for the production of tools and weapons by Upper Paleolithic societies. Sites in Europe and the Levant illustrate the intricate reduction of cores in the process of manufacturing tools through the use of burins and punches, indicative of the level of standardization that existed in production practices under development during this period. The use of grinding and pounding stones also became quite prevalent in terms of their use for food production, typically grains collected by hunter-gatherer bands. The use of weapons, such as spear throwers, boomerangs, and bows and arrows, was also adopted during this period, providing more efficient tools for hunting game. The incorporation of this complex tool kit allowed for the more efficient procurement and production of foodstuffs for early human societies.

Other developments in material culture in Europe and the Levant suggest behavioral changes on the part of early human societies in terms of emergent belief systems. Body decorations, in the form of pendants and beads, indicate that early humans were developing a sense of identity as individuals and as a group. Typically, these were manufactured from shells, ivory, teeth, and ostrich egg shells. Moreover, animal and human figurines manufactured from bone, ivory, antler, and stone begin to appear during this period in rockshelters, caves, and other places of habitation. Cave art, notably in France and Spain, is also indicative of this long-term development of early human culture. More intricate behavior patterns are also suggested by intentional human burial of the dead along with grave goods, which are indicative of changing perceptions on death by early humans and Neanderthals compared to that which characterized preceding Middle Paleolithic burial practices.

Habitations and material sites in Europe and Southwest Asia during the Upper Paleolithic were characterized by semisedentary attributes that differentiated them substantially from the Middle Paleolithic. Storage facilities and underground freezing techniques were used for food preservation and surpluses. Hearths in dwellings made with rocks and used for heat and food preparation also become ubiquitous in the Upper Paleolithic. Moreover, the organization of sites used for different lifeway functions also became prevalent during this period. Areas for food preparation, butchering, sleeping, and stone manufacturing as well as places for discarding waste materials became common in Upper Paleolithic sites. These sites and their spatial organization illustrate the level of organization of labor within early human communities as well as suggest the increasing complexity of societal functions and behavior developed during the Upper Paleolithic. Some scholars suggest that social stratification might have developed during this period as well, given that some burial sites were indicative of wealth, not to mention that certain habitations possessed a greater degree of goods that were not available to all members of a hunter-gatherer band. Nonetheless, based on existing archaeological evidence available to scholars, the Upper Paleolithic in Europe and Southwest Asia is illustrative of the development of lifeways of early humans, characterized by increasing complexity and diversity.

Grinding, Pounding, and Crushing Tools

Although it is likely that our earliest hominid ancestors used simple, unmodified stones to crush

and pound subsistence resources, the use of more formally designed stones for grinding and processing foodstuffs became more common during the Upper Paleolithic. At Qafzeh Cave in Israel, early stone grinding tools were found including a mortar with ochre stains, indicating its use for processing ochre through crushing. Moreover, it also appears that many of these stone tools were used for multiple purposes, serving to grind and pound both food and non-food items for manufacture and consumption. Tools such as the grindstone and the handstone were developed as human populations began to rely more extensively upon plants as a major component of the diet.

While early human societies were still characterized by their foraging activities as hunter-gatherers, the increasing complexity of their tool kits allowed them to process different foods. Barley processing existed as early as 20,000 before the present in the Ohalo II site in Israel, where a basalt grinding stone was found that was used to process the plants for baking. Deep mortars from the Upper Paleolithic Levant, dated from 20,000 to 14,500 before the present, indicate their usage for processing grains for baking and other uses. The growing prominence of grinding tools also suggests to some archaeologists that maximizing food usage, given limited sources, was perhaps an impetus to their increasing use by early societies. As some hunter-gatherer societies became semisedentary before the prevalence of settled agriculture, grinding tools provided a way to process grains and thus create enough provisions through the available cereals found by foraging. Items such as mortars, pestles, and other types of grinding implements became prevalent among these societies.

As Late Upper Paleolithic hunter-gatherer societies developed longer sedentary lifeways in some parts of Eurasia, they acquired a greater reliance on the processing of grains through grinding, pounding, and crushing tools. Grinding slabs, which were large concave grinding tools, may have been developed during this transitional settlement process. In this transition between the Late Upper Paleolithic and the Neolithic, handstones and grinding slabs were more widespread, given that this seems to be a period when the domestication of cereals may have occurred.

As this became a more prevalent practice in the Early Neolithic, these tools became more intricate, with far more craftsmanship utilized in their manufacture. Moreover, given the technological complexity of lithic tool kits during this period, these food-processing tools that developed were also more sophisticated.

Tools Made of Perishable Materials—Bone, Antler, and Wood

Stone tools are most abundant in archaeological sites because stone preserves well under a range of environmental conditions. However, in early prehistory other materials were also used for tool-making, notably wood and the bones and antlers of hunted animals, which attest to the ingenuity of Stone Age people. Such materials, especially wood, are more susceptible to decomposition than stone. Evidence for wooden tools is scarce,

but stone, bone, or antler tools would have been difficult to use without shafts or handles. Consequently, shaped wood was not a tool in itself but instead was one component of a tool together with binding. Specific examples of wooden tools include 400,000-year-old shaped spears of spruce preserved in peat in a coal pit near Hanover, Germany, and a yew spear circa 300,000–200,000 years old in sediments at Clacton in Britain. Wooden tools are more abundant in Mesolithic sites and include parts of an oar circa 8,500 years old from Star Carr near Scarborough, in Britain; throwing sticks, bows, spears, borers, skis, an oar, and sledge runners from Vis I; a peat bog in the Vychegda basin of Ural Russia; and decorated paddles from Tybrind Vig, Denmark.

Debates surround what constitutes a bone tool, the earliest tools so far discovered, and what such tools mean in relation to early human development. Bone points from the South African sites of Swartkrans, Sterkfontein, and Dri-molen are between 1.8 million and 1 million years old. Wear marks suggest that the bones were used as digging sticks, possibly for extracting tubers and/or termites and possibly by *Australopithecus robustus*, an ancestor of the hominids. Bone digging sticks and implements for butchering are evident at Olduvai Gorge, possibly associated with *Homo habilis* (*rudolfensis*) or *H. erectus*. Sediments circa 82,000

► THE KATANDA HARPOONS—EARLY EVIDENCE FOR RIVER FISHING?

The open-air site of Katanda is located in the valley of the Upper Semliki River in Zaire, where two other similar sites of Early and Middle Stone Age designation are found in paleo-floodplain contexts. Direct and indirect radiometric dating methods including thermoluminescence (among others) yielded preliminary age estimates between 65,000 and 90,000 years before the present. Along with a daggerlike implement and faunal material, these sites have yielded formal bone tools including unbarbed bone points and barbed bone harpoons, the latter possibly the earliest known in prehistory. The harpoons were recovered from several sites and seem to be tanged (that is, with a stem) for hafting purposes. The evidence of

fishing in this region is suggested by the stratigraphic association of fish bones, possibly belonging to adult catfish and signifying seasonal exploitation of riverine resources and specialized subsistence behaviors. Though no hominin fossils have been recovered here, behaviorally and biologically modern humans are thought to be responsible.

▶ EUROPEAN UPPER PALEOLITHIC BONE AND ANTLER TECHNOLOGIES

The Upper Paleolithic (ca. 40,000–10,000 years ago) was a period of innovation especially in relation to toolmaking and cultural development in Europe that is categorized chronologically as follows: Châtelperronian, Aurignacian, Perigordian, Gravettian, Solutrean, and Magdalenian industries. Such innovations are attributed to the arrival of modern humans (*Homo sapiens*). The use of bone and antler increased substantially, as did the range and sophistication of tools and toolmaking technology, notably blade tools, the use of jewelry, and representational art. For example, 142 pieces of worked bone, including bird bone, from the Châtelperronian site of Arcy sur Cure, Grotte du Renne, north-central France, include awls, points, pins, and rings.

Bone, ivory spearheads, bone points, and antler bâtons have been found in Aurignacian sites between circa 34,000 and 28,000 years old in France and Germany. The rock shelter of La Madeleine, circa 16,500 years old, in Dordogne, France, has yielded bone tools, which include javelin points, barbed bone points, eyed needles, spears, spear throwers, and chisels of bone, while antler tools include a spear thrower with a handle carved in the shape of a mammoth. Sediments circa 12,000 years old in Gough's Cave in Cheddar Gorge, in southwestern Britain, also contain tools

Reindeer antler carved with deer and leaping salmon, from the Grotte de Lortet, Magdalenian, 15,000–18,000 BCE. (Gianni Dagli Orti/Corbis)

that include a bâton (use unknown) of reindeer antler and a shin bone of arctic fox that had been sharpened and notched to provide an implement for piercing (probably skins/furs for clothing). Such complexity is apparent throughout Europe and reflects planning, skill, and the use and availability of time to undertake painstaking work.

—A. M. Mannion

years old at Blombos Cave, Southern Cape coast of South Africa, contain bone tools (e.g., projectile points and piercing tools similar to awls); these facilitated the stitching of skins for clothing, containers, etc. Early Paleolithic bone tools in Europe include those from several sites in Italy (e.g., sediments from Fontana Ranuccio, 55 miles [90 kilometers] southeast of Rome, and circa 450,000 years old contain bone tool bifaces produced by flaking the long bones of a now extinct elephant, *Elephas antiquus*). At Salzgitter-Lebenstedt, Germany, sediments circa 50,000 to 60,000 years old have yielded a range of tools fashioned from mammoth bones and evidence for systematic exploitation of reindeer, possibly by Neanderthals. Bone (and antler) tools have also been found at Xujiayao, China, that are circa 104,000–124,000 years old.

From circa 40,000 years ago, when the Upper Paleolithic period began, the occurrence of bone tools increases in archaeological sites and is associated with the arrival of modern humans with advanced social strategies including highly organized food procurement. Many Upper Paleolithic and Mesolithic sites contain tools made from wood, bone, antler, tooth, horn, ivory, and shell. These were used as cutting edges for butchering, points for piercing and sewing, and percussive surfaces for breaking bones to extract marrow and making tools. Sites where such tools are present include Vela Spila, a cave on the island of Korkula, Croatia, from where 29 bone tools from Mesolithic habitation layers have been retrieved and that outnumber stone tools in contrast to lower Paleolithic layers. Many are needles, possibly for extracting shellfish from shells,

and some were probably hooks for fishing. Many Mesolithic sites along the western coast of Scotland contain similar bone tools and discarded shells.

The oldest antler tools, used as hammers to fashion flint tools, are from Boxgrove, southern England, where sediments circa 500,000 years old have yielded remains of *H. heidelbergensis*. Otherwise, antler tools are most significant in European Upper Paleolithic sites in association with bone and stone tools.

Projectile Technologies—Spears, the Atlatl, and Bow and Arrow

The origin of projectile technologies begins in the Middle Paleolithic. Their wide and relatively quick diffusion across many societies can be explained in terms of their efficiency as hunting tools and as defensive implements. In effect, these tools allow action at a distance and provide the opportunity for the hunter to hit targets with greater precision and more force. Some researchers even view invention of spears, darts, atlatls, and the bow and arrow as a process which placed humans at the top of the food chain in competition with other predators.

Spears are of two kinds: thrusting and throwing. In practice, these uses can overlap. Early spears, such as those found in Europe and that date to 400,000 years ago, were made of wood. The use of harder tips, such as those made of flint, appear somewhat later in time.

The atlatl (a term derived from Nahuatl language of Aztecs), or spear thrower, is a device that uses leverage to achieve greater velocity in spear throwing. Usually it is thin and flat, is made of bone and antler, and consists of a shaft with a hook in which the butt of the spear rests. Its size and weight depend on the type of animal hunted and the distance at which the animal was engaged. Instead of large spears, atlatls hurl smaller projectiles known as darts that may or may not have been tipped with stone. Skilled

hunters could hurl a dart at distances more than 300 feet (100 meters) with great accuracy. The atlatl was often decorated (carved, painted, or designed), and some modern examples have special inclusions made of leather, plant fiber, or small stones, probably for better balancing.

The earliest known atlatl was found in northwestern Africa and is dated to about 25,000 years ago. It became widely distributed in latter phases of European Late Paleolithic in the Solutrean and Magdalenian technocomplexes. The atlatl, however, was likely to have been reinvented numerous times in the past.

The invention of the atlatl is regarded as a very important step toward the development of small projectile points. As the bulk of elastic energy is stored in the throwing device rather than the projectile, the size of flint inserts on the dart or spear could be made smaller, which offered ancient people a means to standardize their hunting implements and to conserve raw materials.

During much of the twentieth century, the origin of bow and arrow was believed to date to the Mesolithic in Europe, or sometime after 10,000 years ago, when large mammals disappeared as the glaciers retreated. As such, the bow and arrow were seen as a technological innovation that made the hunting of smaller animals more efficient.

However, recent discoveries in Africa leave little doubt that the bow and arrow were probably invented in the Late Upper Paleolithic, perhaps as early as 18,000–20,000 years ago. The best evidence for this comes not from the bows but from projectile points that were too small to place on spears or darts. The assumption is that these were used to tip arrows. Like the atlatl, the bow and arrow were probably invented numerous times and at very different times.

Archaeological data (in particular, scarce findings of wooden and slightly more abundant bone artifacts) led to distinguishing two types of bow used during the Late Paleolithic and Mesolithic: the simple form was made of one piece of wood, while the complex form consists of three pieces of wood, bone, or antler. The choice of a particular material depended, most probably, on the availability and quality of raw material and, in some cases, the intended function of the implement. Bow dimensions differ greatly: archae-

ological and ethnographic specimens are as large as 6.6 feet (2 meters) or as small as 15.7 inches (40 centimeters) in length. Arrows may be simple: a shaft with or without a tip, or composite, and composed of a tip and shafts of different sizes.

Darts, the atlatl, and bows and arrows are widely used nowadays by the aboriginal population of North America, Australia, New Guinea, and other territories where hunting is still important as a subsistence procurement strategy.

Fiber Technologies, 100,000–10,000 BCE

"Fiber technologies" refers to the discovery that plant and animal matter may be treated in such a way as to produce nets, ropes, and cloth. Evidence for fiber technology (otherwise known as textile production) comes from such archaeological sites as Çayönü, Turkey, excavated by archaeologist Robert Braidwood and dated to approximately 7200 BCE. At this site, Braidwood's team found a piece of cloth wrapped around an antler. Gillian Vogelsang-Eastwood, of the National Museum of Ethnology (Leiden, Netherlands), identified the cloth fragment as flax that had been soaked in water and rotted somewhat in order to extract and separate its fibrous content, a process that is still necessary to this day in the manufacture of plant-composed fabrics. Potsherds from these sites also bear decorative impressions of both twine and fabric. Similar textile fragments were discovered at several Turkish sites and in Israel that date to approximately the same time period. Animal hair and plant fiber artifacts of rope and cloth were also found at sites in central Europe and Russia dating to between 31,000 and 25,000 BCE.

It is not known if weaving with animal hair precedes the use of plant fibers or the reverse. Perhaps both technologies developed in tandem.

However, various plant fibers (jute, hemp, cotton, nettles) are suitable for the production of textiles, and the development of plant fiber technology everywhere retains the same basic characteristics. First, the desirable fiber crop is uprooted, bundled, and dried by the sun. The seed is then separated from the fibrous mass, which is then subjected to a process called retting wherein the fibrous material is soaked in water again and allowed to rot, which may take from several days to a month depending upon the character of the fibers. When the bark of the stems can be peeled away from their core, the plant material is again dried and then pounded with stones to crush it so as to separate the fibrous filaments. These filaments are then combed in order to align the fibers, which are then drawn out of the mass and twisted into threads by means of spinning. Stone hand-spindles are further evidence for textile manufacture at the aforementioned Turkish, Israeli, and Russian archaeological sites.

Threads and yarns drawn out and twisted by means of spinning are then cut to suitable lengths and woven by means of the interlacing of threads at right angles, of which the longitudinal threads are called the warp and the transverse threads are called the weft. The wooden device for facilitating this process is called a loom. The first looms were made of wood and were handheld and portable, suggesting that a sedentary lifestyle is not a prerequisite for this human invention.

Structures

The livelihood and subsistence strategies of early modern humans were based mainly on extensive exploitation of their foraging territories, implying regular, usually seasonal, movement. As a

► THE GRAVETTIAN STRUCTURES AT KOSTENKI

In Stratum 1 of Kostenki 1 (in the Don River valley of central Russia) are found remnants of two oval outlines usually interpreted as dwellings (living structures). A series of deepened hearths marks their long axes. Walls also were marked by specially prepared (curved) big mammoth bones and tusks planted into the earth. They were practically vertical, but their curved shape produced an overhang in the interior of the dwelling.

Gravettian structures at Kostenki were discovered as early as the 1930s, and since that time their social interpretation remains in dispute. Most Soviet researchers believed that they reflect an occupation by the whole community with common storage. On the other hand, based on results of newer studies of analogous structure at the Pushkari I site on the Desna River, one cannot exclude the possibility of their interpretation as a series of very close small dwellings (every one with its own hearth) connecting the livelihoods of separate but closely related families. The first model implies common procurement and consumption of resources, while the second suggests a pattern of sharing within smaller families while living together in a larger community group.

Reconstructions of these structures are on exhibit in an open-air museum near the site.

► THE MAGDALENIAN STRUCTURES AT MEZHIRICH

The settlement of Mezhirich is situated on the high promontory at the confluence of the Rosava and Ros rivers near Kiev, Ukraine, and traditionally is connected with mammoth hunters of the Epigravettian tradition (including the Mezin archaeological culture) in the Middle Dnieper region.

Four household complexes have been excavated there since the end of the nineteenth century, each consisting of a circular dwelling surrounded by storage pits, open-air hearths, places of flint tool production, and bone and hide processing.

The dwellings were large (up to 16 feet, or 5 meters, in external diameter), and their sides were made of long mammoth tusks and bones. It is likely that hides covered the bones to seal out cold and weather. Both mammoth tusks and skulls were used as construction elements; in one structure,

over 17 tusks and 95 skulls were used. The careful placement and fitting of the tusks and skulls, which were often trimmed and cut, suggest that a great deal of effort and thought went into the construction of these houses.

The interior of the dwellings contained hearths and storage pits. Remains of lamps (made of mammoth's patella) suggest the use of fats or oils to light them. Plenty of flint, bone, and ivory artifacts have been found there together with ocher and amber. Female figurines and ornamented bones were also found in the structures.

THE PRE-CLOVIS STRUCTURES OF MONTE VERDE

The pre-Clovis structures found at Monte Verde, located in south-central Chile and dating back to circa 10,500 BCE, have provided modern scholars with significant insights into the settlement patterns of early Americans. A wishbone-shaped structure comprised of compacted gravel and sand was found on the site's lowest stratigraphic level. The structure also has a semirectangular platform protruding from the exterior side of its base, with evidence of an entryway opening to the southeast. Two hearths have been found on the floor of the structure, and the remains of a center pole 16.5 inches (42 centimeters) long were recovered from inside the structure. Furthermore, vertically arranged branches about 1–3 inches (3–8 centimeters) in length were recovered from the middle of the side walls, which scholars believe are the remains of walls made of branches. Archaeologists have also recovered evidence of a tentlike structure that is 65.6 feet (20 meters) long. These findings indicate that the frame was made of logs and planks anchored by stakes and that the walls were poles covered by animal hides. Inside the tent, planks and poles divided individual living spaces. Outside the tent two large communal hearths were found, along with a store of firewood, wooden mortars, and grinding stones.

result of this mobile existence, like modern hunters and gatherers these ancient peoples made extensive use of structures of different kinds.

Traditionally, dwellings are defined as natural or artificial constructions that vary widely in the materials used to build them, taking into account climate, occupation duration, and site function. Four basic types of prehistoric dwelling are recognized: wind screens, pit dwellings, surface dwellings, and rockshelters or cave dwellings.

Wind screens are simply animal hide, fabric, or vegetation frames used to shield people from wind or blowing dust. Although the screens themselves are not preserved in the archaeological record, patterns of artifact deposition suggest that people routinely performed activities behind them.

Pit dwellings are defined by relatively shallow excavations in the soil surface. Within them,

hearths and other features of daily life are found. Their superstructures tend to be conical or circular in form and were likely composed of wood, bone, or other perishable materials. These were then covered with brush, animal hides, mud or earth, and similar materials. Pit structures were often constructed in cold windy climates.

Surface dwellings are the most common type of structures found at Paleolithic settlements. Archaeologically, they are traced via accumulations of bone and stone artifacts, along with hearths and fauna that define their edges. In their simplest form, they resembled modern tents configured into different shapes. However, occupations of long duration were more substantial, and good examples of these are the Late Paleolithic dwellings of central Europe and of the central Russian Plain. Here, skulls and long bones of mammoth were used to create the

framework for the structure, which was then covered with hides.

Cave dwellings are restricted to mountainous areas or locations where the local geology favors their formation. Caves have dark zones (interiors where natural light does not penetrate), while rockshelters are best described as overhangs that create sheltered spaces, sometime quite large, beneath them. Rockshelters tend not to have dark zones. Beginning in the Middle Paleolithic, humans began to use both extensively, and during the Upper Paleolithic, deep interiors of caves were used for ritual activities. While humans may have used the mouths or entrances of caves, their deep interiors have never been used for habitation. Instead, people often constructed surface shelters at cave entrances and conducted most of their daily activities in them.

In most cases structures were closely integrated with outside hearths, working places, and storage and garbage pits. Together, these complex artifacts aid the process of reconstructing the daily lives of ancient peoples.

The Origins of Clothing

Because modern apes are covered in fur, we know that our ancestors were too. At some point along the hominin evolutionary path, however, our body hair thinned out drastically even though we retained the same number of hairs as apes and monkeys have. It is possible that this hair reduction, this transition to being a naked ape, according to a hypothesis offered by Nina Jablonski, occurred when hominins achieved completely bipedal bodies around two million years ago. A great climatic shift occurred about then, at the beginning of the Pleistocene epoch, causing much of sub-Saharan Africa to become

drier and to become more seasonal as well. The grasslands that characterize much of East Africa today became common, prior to which forests were the norm. Hominins like *Homo ergaster* or *Homo erectus* were eating more meat and bone marrow and may have been actively scavenging and hunting for long days under the hot sun on these savannas full of grazing herbivore prey. Being naked and being able to sweat profusely would have been advantageous to keep body temperatures down. Clothing may have been helpful for desert nights or at high altitudes, but there is no evidence for such a thing. Nor is there evidence that *H. ergaster* or *H. erectus* dispersed to higher latitudes in more temperate climates like those found at Dmanisi, Georgia, or wore anything on their bodies. That is not to say that they did not, but there is no evidence, and there was not necessarily good reason to wear anything. If the practice of wearing clothing originated out of the need to keep warm, it is not until very late in the story of hominin evolution that people would have needed it.

People of the Middle Paleolithic, the so-called archaics that included transitional *Homo sapiens* and *Homo neanderthalensis*, were the first to adapt to colder climes in central and western Europe. Upper Paleolithic humans, in the Late Pleistocene, were then the first to inhabit lands with long cold winters like easternmost Europe and North Asia. Therefore, it is definitely by this point that cultural innovations, like using fur and tanning hides for clothing and for housing, would have been useful. Some Upper Paleolithic sites in Russia, like Kostenki XIV, contain skeletons of fur-bearing animals like wolves and foxes. Sometimes entire skeletons are preserved but are missing the bones of their paws, and other times all that remains are the articulated bones of the paws. Modern hunters often leave the small bones of the paws inside the skins when removing them from a carcass, and this is how these archaeological remains are interpreted. However, at these sites it is unclear whether the skins were used for insulating a hut, closing off a cave opening, or insulating a person. Regardless, by about 70,000 years ago people were probably draping, wrapping, and tying furs and skins around their bodies, and some Upper Paleolithic tools are interpreted to have been used as awls

➤ WHAT CAN BODY LICE TELL US ABOUT CLOTHING? (100,000–10,000 BCE)

Recent DNA studies of body lice (*Pediculus humanus corporis*) by molecular geneticists and physical anthropologists propose the hypothesis that both lice and clothing originated in Africa between 72,000 and 40,000 BCE in a parasitic relationship. This correlates with an earlier hypothesis by Rebecca Cann, Mark Stoneking, and Allan C. Wilson (1987) based on DNA studies, maintaining that anatomically modern humans (*Homo sapiens*) are descended from one woman who migrated with her band from Africa to Europe within this same period.

The Kittler study examined DNA sequences obtained from two mtDNA segments and two nuclear DNA segments in 14 body lice from 12 geographic areas. Concocting a “molecular clock,”

the evolution of body lice and the inception of clothing manufacture was dated to the European and Asian expansion of *Homo sapiens* with the proviso that clothing may have existed before lice exploited this “ecological niche.”

and punches, useful for sewing skins together. Dated to about 19,000 years ago, there are bone needles with eyes for threading that were certainly used for making clothing.

Impressions of clothing from Upper Paleolithic burials are the earliest best evidence for what people were actually wearing. All that remains is a pattern of soil discoloration along with beads strung around the skeletons of three people buried at the site of Sungir, Russia, dated to at least 22,000 years ago. It is possible to make out the beaded leather ensemble complete with hat, shirt, coat, pants, and shoes. That the earliest preserved clothing, albeit discolored soil and beads, is decorated lends strength to the hypothesis that clothing did not so much originate from the need to protect the body as it arose from the need to adorn it; clothing is a form of communication. When exactly people began to weave plants into textiles is not known either, but the latest evidence from the foothills of the Caucasus Mountains is helping to change that. Flax fibers that were once part of a colorful woven textile have been recovered from a cave site dating to as old as 36,000 years ago.

Clay and Ceramic Artifacts

The oldest known ceramic artifacts are baked clay figurines from the Czech Republic, which date to 26,000 years ago. These nonutilitarian objects, called Venus figurines, were made by shaping moist clay into female forms and then drying and heating them to a hardened state. The first utilitarian ceramic vessels appeared independently around 12,000 years ago in Japan, 10,500 years ago in the Near East, and 3,000 years ago in the New World. Ceramic artifacts are relatively well preserved in the archaeological record because they are fired. Unfired clay items are easily broken down but in exceptional cases survive. Most clay artifacts are nonutilitarian figurines.

To create ceramic artifacts, three important principles of clay must be known: moist clay can

be molded and when dried will retain that form, the dried clay artifact will harden when heated or fired, and by adding different materials to clay its natural properties and utility can be improved. Improvement in ceramic manufacturing techniques over time reflects an increased knowledge of these principles as well as technological advances. By closely examining ceramic artifacts, archaeologists can tell the clay mixture used, how the artifact was formed and fired, and often its function. Moreover, the shapes and styles of the pieces are frequently associated with particular cultures and chronological periods.

Clays consist of decomposed silicate rocks that contain a high percentage of alumina, such as micas and feldspars. They are found either in their primary location, where the rock weathering took place, or at a secondary location due to transportation by water or other forces. The different clay colors come from impurities in the deposit. White clays typically lack impurities, while gray to black clays likely contain organics. Red, brown, buff, and yellow clays are created by the addition of oxides and hydroxides. Clay color can change during the firing process, however. Organic rich black clay, for example, will change to red-brown or white when fired because the organics are burned off. The addition of organic or inorganic materials to clay can reduce shrinkage and cracking during firing. Called tempers, these agents are also important because they may be culturally specific, as can the clays. Chemical analysis of ceramic artifacts can help source the raw clays and tempers used and often aids in the reconstruction of trade networks.

With the clay fabric prepared, the next step in ceramic production is forming the item. Vessels were made four ways: modeling, coiling, molding, and throwing. The earliest artifacts were modeled by hand, generally starting with a ball of clay that was pinched into shape. Coiled artifacts were built up from a base using long clay coils that were joined together. These and the modeled vessels were finger smoothed or finished using a paddle and an anvil. Molded vessels were formed by pressing a rolled piece of clay into a concave mold or onto a convex mold. This allowed for the production of a large num-

ber of similar artifacts. The invention of the wheel around 5,500 years ago in the Near and Far East revolutionized ceramic production. A skilled potter was then able to throw vessels in a fraction of the time.

A number of decorative finishing techniques were applied to the vessels before and after firing. Before the vessels were completely dry they could be burnished, polished, or decorated by impressing objects into the clay. Color could be added before the vessels were fired by slipping or painting the items or by painting them afterward. The firing environment also plays a role in the final color of the artifact. In an oxygen-rich atmosphere the colors of the paints and clays are revealed, while in reduced atmospheres lacking oxygen the pieces are often grayed.

To avoid cracking the vessels during firing, the clay artifacts had to be completely dry. Any remaining water in the clay fabric was then driven off in the dehydration period of firing. At this stage the clay artifacts were placed in a low-temperature environment (approximately 200 to 400 degrees Fahrenheit, or 100 to 200 degrees Celsius) for several hours. The second firing stage at a higher temperature, called the oxidation period, is when any organic temper was burned off. The final vitrification stage was only reached when the clay particles fused together. This process begins between about 1,500 and 1,650 Fahrenheit (800 and 900 degrees Celsius) and is completed at about 2,192 degrees Fahrenheit (1,200 degrees Celsius).

A basic ceramic analysis looks at the clay and temper of the artifact, the manufacture technique(s) used, the finishing applied, and the firing stages. Moreover, an analysis of the style and form of the vessel and any residue remaining can reveal the function of the artifact. Together, technology, form, and style are culturally and chronologically specific.

The Technology of Cave Painting

The earliest cave paintings were created by *Homo sapiens* 32,000 years ago. More than 200 caves in France and Spain alone depict visually accurate portrayals of Ice Age mammals including bison, aurochs, horses, mammoths, and deer. Geometric designs and hand prints are also common. The animals in the paintings are often drawn two-dimensionally, although some artists made use of the cave features to create a more three-dimensional perspective. Many of the paintings are found toward the backs of the caves, where the wall surfaces were of better quality, and the artworks were hidden from casual view. Sandstone lamps in which animal fat was burned were found in a few of the caves. These lamps would have burned for several hours, providing adequate light for the artists.

Through the experimental work of cave art specialist Michel Lorblanchet, the technology of the artists is now recognized. Lorblanchet discovered that there were two main ways that the artists applied paint to the cave wall. The first was to spit the paint, with or without a hollowed tube, onto the rock using an object such as the hand, a piece of cloth, or a feather as a screen. When the item was removed, a negative image remained. To create dots, an animal skin with a hole punched through it was held against the rock wall. The second method involved making a brush by chewing the end of a twig. The painter then used it to create the artwork, though this technique was not as effective if the cave wall was too uneven. On careful inspection of cave art, it is clear that the spit technique was more commonly used. Many of the paintings have a sharp edge on one side and a fuzzy edge on the other, created by spitting with a screen held against the cave wall. Hand screening was long inferred by archaeologists, but the use of this technique for the detailed animal and geometric drawings was enlightening.

Chemical analyses of the different paints have confirmed their components. Charcoal and manganese oxides were used to create black. They were ground using limestone blocks and then mixed with talc, a mixture of barite and potassium feldspar, potassium feldspar alone, or

potassium feldspar mixed with an excess of biotite. These extenders helped bring out the color of the pigment and add bulk to the paint. The powdered blend was then mixed with water or saliva. To create red paint, ochre from iron-rich clay, natural hematite, or heated goethite were used, while yellow, although less commonly used in cave art, was made from goethite. Animal fat may have also been used in the mixtures, but these paints are more likely to be associated with the brush technique.

Several hypotheses as to the meanings of the ancient cave paintings have been suggested, ranging from shamanistic control over the animals (hunting magic) to simply art for art's sake. Unfortunately, only speculations can be made. Their true meaning(s) may never be known.

Early Notational Systems

The reconstruction of the origin and beginnings of early notational systems began with Alexander Marshack in 1972, and since that time his ideas remain the basis for the analysis of this aspect of the cultural behavior of Paleolithic peoples.

Although cut marks on bones due to butchery practice are common, the cuts and notches described by Marshack were distinct from these in that they were often found on the shafts of the long bones of animals and as such had no apparent utilitarian purpose. Such notched bones were thus included in the corpus of mobiliary (portable) art of the Paleolithic peoples of Europe.

Using a microscope, Marshack noted that the notations were made by different tools. This

➤ MAGDALENIAN NOTCHED BONES

The beginnings of information technology in the cultural history of modern humans can be found in the notational systems of the late Paleolithic Age. This was a time when the ice shield in the northern regions of Europe began to melt, marking a period of significant climatic and cultural transition.

While the earliest engraved objects from the Ice Age were decorated with realistic images, notched bones from the latter phase of the Magdalenian period, circa 17,000–10,000 BP, were carved with abstract signs carefully composed in specific groupings and alignments. This intentional arrangement of nonrepresentational signs suggests a deliberate system of notation used to encode specific information.

The categories of linear signs engraved on notched bones—such as lines (horizontal and vertical, long and short), dots, and scaling measures (long, straight, or curvy lines with markings of gradation)—have been widely interpreted as comprising an early calendrical system used for measuring the phases of the moon and seasonal cycles. On a notched stick from the Cave of Cueto de la Mina (Asturias, Spain) dating to circa 13,000 BP, for instance, the intervals between the phases of the moon are recorded throughout most of the year, from mid-February to the end of October.

implies that they were done by different individuals or by the same individual but at different times, and thus these marks could reflect corresponding calculations of time. The next step was to track the regularities or patterns of these notches. Marshack claimed to have detected daily, lunar, seasonal, and ceremonial cycles in patterns of notches. In Marshack's terms, they represent stored (i.e., already transpired) events that had no apparent connection with resource and fertility magic.

The necessity to develop notational systems was probably caused by the needs of everyday life. Based on the analysis of portable art objects found at Late Paleolithic sites of Europe, at least two notational systems were practiced at that time: one based on units of five and likely associated with the number of fingers and toes of the human body and the other based on seven units, probably reflecting awareness of four lunar phases consisting of seven days each.

Abstract notation is thus best understood as an aid to memory (collective as well as individual). Such systems helped hunters and gatherers maintain a sense of the timing of seasonal changes critical to their survival. As early agricultural societies emerged, simple notational systems eventually evolved into calendars that helped to predict crucial events in the timing of the agricultural cycle, such as when to plant and to harvest. Notational systems also played a role

in the emergence of ritual calendars or cycles, which were often connected to those related to subsistence events.

■ Introduction: Tools and Technologies of Modern Humans, 10,000–4000 BCE

By 10,000 BCE modern humans had migrated to every continent on earth and possessed a number of technologies and tools that allowed them to rapidly adapt to each environment they encountered. In some locations these technologies and tools enabled them to settle in one place for extended periods of time. As a result, humans were able to not only refine their current tool kits but also develop a wide array of new technologies and tools for the first time. New technologies to emerge beginning around 10,000 BCE included plant and animal domestication, agriculture, permanent to semipermanent architecture, the preservation and long-term storage of food, ceramics and pottery, and sophisticated farming, hunting, and gathering technologies, each of which required a variety of new tools. However, not every group developed the same technologies at the same time, nor did all these technologies develop in all regions of the world. For example, the earliest farming societies in the Middle East did not use pottery, while in parts of Europe and Britain it remains unclear to what extent plants were domesticated or whether permanently settled communities existed. In other parts of the world, such as in Asia, Southeast Asia, and the Americas, independent domestication events of plants and animals led to regionally distinctive cultures that arose completely independent of those in Europe and the Middle East.

Beginning around 9000 BCE in parts of the Middle East, Europe, North Africa, and Asia, domestication of both plants and animals emerged as one of the most powerful new technologies to be developed by modern humans. At first domestication was limited to a narrow range of plants, such as wheat, millet, and spelt, as well as animals, including dogs, sheep, and goats. Soon after, however, cattle and pigs were domesticated along with barley and rice. In the Americas, evidence indicates that domestication of plants and animals as well as agriculture was independently invented from that of the rest of the world at a slightly later date. Beginning around 6000 BCE squash, corn, and some tubers may have been domesticated, and by the end of the period archaeological evidence indicates that beans, turkeys, and the alpaca were also domesticated. In New Guinea and parts of Southeast Asia sugarcane, bananas, and species of taro and yams were domesticated by 6000 BCE, while there is no evidence that domestication of any plants or animals occurred in Australia, parts of southern Africa, or the Pacific Islands during this period. As this technology developed, many new tools associated with farming, agriculture, and animal husbandry are recorded in the archaeological record for the first time.

New tools associated with the tending, harvesting, and processing of crops to first emerge during this period include sickle blades and

grinding stones, pottery and ceramics, specialized bone and wood implements, mortar and pestle, and other tools associated with the production and long-term storage of food and animal husbandry. Modern humans also manufactured for the first time a range of other types of new stone tools and ornaments, including increasingly smaller projectile points, beads, statuettes, fishhooks and net weights, and polished stone tools such as the ax, adze, and other items. In turn, many of these new tools and technologies allowed modern humans to begin to alter the landscape and environment around them in new and profound ways. For example, in Europe the development of the adze and polished stone ax allowed humans to clear large swaths of forest for farmland as well as to use wood for structures, shelter, and watercraft. In parts of the Americas, Southeast Asia, the Middle East, and North Africa, modern humans began to control the flow of water in some locations as well as to create areas of farmable land through terracing, plowing, and irrigation. Likewise, evidence of stream and coastal shore modification for fish traps has been recorded in the Americas, Australia, and Africa.

The domestication of plants and animals along with agriculture also allowed people during this time to settle into permanent or semi-permanent communities, where evidence of permanent architecture is first seen during this period. In the Levant, Anatolia, Syria, northern Mesopotamia, and central Asia, evidence of mud-brick technology to construct houses and villages first appears. In some locations, such as Çatalhöyük in Turkey dating to around 6500 BCE, this technology was developed to such a degree that individual houses were constructed, plastered, and painted with elaborate scenes of humans and animals. In Europe, longhouses built from wattle and daub technology were constructed, although by 6000 BCE wood houses became more common in certain parts. People in the British Isles also built long barrows and chamber tombs for their dead out of stone and also constructed causewayed camps, henges, flint mines, and large stone monuments. In the Americas, evidence of permanent architecture does not emerge until the end of this period, while in Australia, sub-Saharan Africa, the

Pacific Islands, and northern Asia there is no evidence of this technology during this period.

In coastal areas of the Indian Ocean, the Arabian Gulf, and North and South America, the technology associated with line and net fishing first appears during this period. Shell and bone fishhooks as well as nets and line weights are first recorded in the archaeological record beginning around 7000 BCE, while technology to exploit shellfish and mollusks emerged a little earlier and in more places, including Australia, Japan, and the Mediterranean. Finally, nonutilitarian objects such as statuettes, beads, stone disks, and other items become much more common during this period and have been recovered from all regions of the globe. Although some items have been dated prior to 10,000 BCE, it is not until this period that there is archaeological evidence of mass production and specialization in nonutilitarian tools.

Increasing Diversity and Complexity of Human Technological Organization

The emergence of *Homo sapiens* during the Upper Paleolithic and the adoption of the tool kits of preceding hominids contributed to the increasing complexity and added diversity of technology. The organization of human tool kits was shaped by further innovations in the manufacturing of stone tools, the development of more complex composite tools, and the use of antler, bones, and wood as elements of such tools. With the inception of hunter-gatherer societies and then the subsequent development of settlement agriculture, technological advances in terms of manufacturing, techniques, and actual tools underwent

significant advances, given the adaptations to lifeways by modern humans albeit in different world regions at distinct times. Nonetheless, this process is illustrative of the dynamic nature of technological innovation in early human societies amid their increasing complexity.

Hunting, foraging, food production, and other aspects of early human lifeways were characterized by myriad technological innovations. As early hominids adapted to their environments by developing into hunter-gatherer societies, their technology, in terms of new tools and inventive techniques, underwent drastic changes. During the Upper Paleolithic, early *Homo sapiens* foraged and hunted across vast regions, typically in bands, following migration patterns of game and seasons. Building on the technological framework of their *Homo erectus* predecessors (Acheulian culture) and Neanderthal (Mousterian culture) contemporaries, *Homo sapiens* acquired a fairly complex tool kit of sophisticated composite tools composed not only of stone but also of bone and antler. Moreover, such technological innovations allowed for a more complex lifeway than that of prior hominids. While they did continue along hunter-gatherer lifeways, their new tools allowed them to be far more effective hunters and to make better use of animal parts as integral elements for tools and other wares for daily life. Thus, such technological innovations in terms of tools and new techniques reflected the evolving complexity of early human hunter-gatherer societies across much of Afro-Eurasia during this period.

Prior to the development of the early civilizations along the Levant, *Homo sapiens* was able to develop certain technologies prior to the transition from hunter-gatherer societies to that of settled agricultural communities during the Upper Paleolithic. From approximately 35,000 to 8000 BCE, as evidence found in rock shelters and caves in France and Spain suggests, hunter-gatherer cultures developed tool kits far more complex than that of the Mousterian cultures of the Neanderthals. These implements, namely harpoons, bone hooks, spear throwers, and clubs, allowed them to hunt reindeer and other game as well as fish for salmon along nearby rivers. While such hunter-gatherer societies continued to follow the game along with the seasons,

they were equipped to acquire food in any given environment with their sophisticated tool kits, which utilized parts of their kill, wood, and stone. This contributed to the versatility of the lifestyle of early humans in allowing them to adapt to climate in their quest for sustenance.

The development of exchange networks in the Upper Paleolithic, particularly in the Levant and Europe, illustrates the level of interaction between hunter-gatherer societies as crafts and goods became more specialized and utilized as a means of trade. By the end of the Pleistocene in parts of Europe and the Near East, the establishment of semipermanent settlements by seasonal hunter-gatherer societies were characterized by the use of microlithic food-processing tools, such as grindstones. For example, the Natufian culture, which encompassed a region between southern Anatolia to the Nile Valley, used such implements and techniques to process wild cereal grasses. Moreover, their tool kits also included picks and flint sickle blades (mounted on bone handles), used for harvesting. Their lifeways were also characterized by the use of storage chambers in their dwellings along with bowls, mortars, and the development of decorative elements to their tools, which suggest a far more complex lifestyle as they transitioned into semisettled societies. By 8500 BCE, the semipermanent Natufian farming settlement of Jericho in the Levant displayed many of the sedentary characteristics of later fully settled agricultural communities. Trading activities in obsidian, sea-shells, and bitumen were also practiced. Their food-production tool kits, agricultural developments, and the establishment of exchange networks allowed them to remain in the settlement for a longer period of time. Such semiagricultural communities, which would later characterize many of the precursors of the later civilizations that would span Afro-Eurasia, are examples of the relationship among developing human technological organization, the amplified diversity of tool kits, and the increasing complexity of human lifeways.

Fully settled agricultural communities, spanning across Afro-Eurasia, were characterized by the adoption of food-storage facilities, nonsubsistence occupations, and the establishment of organized political structures. While hunter-gatherer

societies continued to exist during this period, the development of settled agriculture provided a far more viable opportunity for the expansion and diversity of technological innovation. The construction of dwellings, artwork, and other urban amenities became integral characteristics of settled agricultural communities. This was due to the specialization of occupations not directly associated with farming (or hunter-gathering) but necessary for the increasing complexity of sedentary lifeways. Such urbanized lifeways were further characterized by the use of new materials, such as earth and plants, for the purpose of construction, as technological innovations for sedentary living.

Transformations in Stone Tool Technologies

The long-term development of stone tool technologies from the earliest hominids to modern man reflect the increasing complexity of prehistorical societies from *Homo habilis* to *Homo sapiens*. The use of stone implements for myriad tasks initially developed approximately two million years before the present. Multiple archaeological findings from Olduvai, Acheulian, Mousterian, and Upper Paleolithic cultures have allowed archaeologists to trace the long-term evolution of stone technologies use by hominids through much of this period. Through this evidence, archaeologists have pieced together the manufacture, types, and uses of stone tools used by hominids. Moreover, through these findings, scholars have also been able to determine how and why these stone tools are illustrative of the lifeways of these early societies and their day-to-day activities.

Archaeological evidence at Olduvai Gorge in East Africa, where British archaeologist Mary Leakey excavated a significant amount of arti-

facts, stone tools, and animal bones, illustrates the earliest examples of stone technologies utilized by *Homo habilis* as early as two million years ago. This concentration of stone tools around animal bones in Olduvai indicates that they were imported there from elsewhere, illustrating that they were used by hominids for the purpose of processing meat for consumption. These tools suggest that they were used to cut animal skin too tough to be cut with teeth. While Olduvai tools look crude in their shape and look like fractured rocks, they do possess characteristics that illustrate their functions as scrapers and cutting tools. From this evidence, it is known that Olduvai hominids were indeed skilled stone toolmakers and were able to make weapons, tools for cutting animal flesh, and scrapers for making tools. Similar tool kits have been found elsewhere in Europe and Asia.

The Olduvai tool kit of choppers, scrapers, and flakes lasted for nearly 1 million years until about 1.5 million years ago, when it was gradually replaced by Acheulian stone technology. Among the major developments that characterized the innovation of the Acheulian stone tools is the stone hand ax. This Acheulian hand ax technology was named after the French town of Saint-Acheul, around which such tools were first found. This technology is mostly associated with *Homo erectus*. The hand ax, unlike Olduvai choppers and scrapers, had to be crafted with greater precision rather than imprecise hammer blows. Hand axes came in a myriad number of shapes and sizes, evidence of their value as tools for *Homo erectus*. Moreover, they were diffused over a vast area of Afro-Eurasia (e.g., northern Europe, sub-Saharan Africa, the Near East, and South Asia), ranging from finely crafted forms to more crude versions. Hand axes were used not only to skin and butcher game but also to grub roots, for woodworking, and for scraping skins. One major advantage of hand axes was that they could be sharpened again for reuse or crafted into smaller flake tools. Some archaeologists, such as Eileen O'Brien, suggest that it was possible that this hand ax could also serve as a projectile tool for hunting large game.

During the same period that the Acheulian hand ax gained prevalence in some areas of Afro-Eurasia, the chopping tool tradition of the

Olduwan variety continued and expanded into other world regions. Evidence from the Zhoukoudian site (occupied from approximately 460,000 to 230,000 years before the present) in China illustrates that *Homo erectus* in East Asia continued to use chopping tools, although they were far more sophisticated than those used by the Olduwan culture, as they were smaller and far less crude. Moreover, choppers were the tool of choice, rather than hand axes, in central Europe, South and East Asia, and eastern Britain.

Mousterian stone technology, developed under the Neanderthals, was more complex than that of the Acheulian variety in technique and level of complexity. Neanderthals developed far more intricate manufacturing techniques for their stone tool kits. They were the first hominids to use prepared core techniques, which essentially allowed them to take standard-sized stones and reworked them into specific tools. Moreover, they were also the first to manufacture composite tools, which were composed of more than one part, such as spears (with spear point, spear shaft, and the binding that connected them). Most Mousterian stone tools consist of flakes, mostly points and scrapers, utilized for hunting, woodworking, and the preparation of skins. These fine tools were carefully crafted at a relatively higher level than that of the preceding Olduwan and Acheulian stone technologies. In French sites, the diversity of Mousterian tool kits suggests that a variety of skills and tasks for different activities are evidence of increasing social complexity on the part of Neanderthals in the Middle Paleolithic.

By the Upper Paleolithic period, *Homo sapiens* had adapted the stone technologies of prior hominids to a vaster array of stone tools and implements, suggesting the increasing complexity of their lifeways. Upper Paleolithic hunter-gatherer societies created highly specialized tools, such as harpoons, retouched points, and graving implements. Such major technological changes have been researched by archaeologists at sites such as Shandidar in Iraq and Mughareh el-Wad in Israel. Major innovations in Upper Paleolithic stone technologies include the use of far more composite tools than Neanderthals (such as the bow and arrow), punchstruck blades, and a more vast range of toolmaking

items, such as bone and antlers. Upper Paleolithic tools were mainly manufactured by punchstruck blades, which were crafted by a punch, a tool that specifically was directed at a single point of the core. Scrapers and burins, which were both smaller tools, were made in this fashion. Burins were used to groove wood, antlers, and bones into spear points and harpoons, part of the innovative composite tool kits of the Upper Paleolithic. Such technological advancements allowed *Homo sapiens* hunter-gatherer societies to develop far more levels of complexity than prior hominids.

Innovations in Ceramics, 10,000–4000 BCE

The Neolithic Age (10,000–4000 BCE) designates a time of remarkable innovations in the development of human technologies, one of which was ceramic manufacture (the exposure of pottery composed of clay mixed with other materials to very high temperatures). So important is this technological advancement that many archaeologists divide the Neolithic Age into two time periods, terming the earlier dates (approximately 10,000–6750 BCE) the “pre-ceramic” or the “a-ceramic” Neolithic. The second time period, the “ceramic Neolithic,” begins roughly after 6750 BCE according to archaeological excavations at some of the most ancient and continually occupied Neolithic sites known to science, those of the Near East and the Levant.

Before humans began to work clay, liquids were held in such naturally occurring products as gourds and coconuts. Where these did not grow, leather pouches stored and transported water. Baskets woven from various grasses carried nonliquid foraged plant matter (berries, nuts, undomesticated grains) from the wild back to the domestic household. Bowls and drinking

➤ JOMON IN JAPAN, 10,000–4000 BCE

The term “Jomon culture” refers to a type of pottery found throughout the Japanese archipelago characteristically having rope impressions. Thus, archaeologists refer to the people who made it as “the Jomon.” Although the period 10,000–4000 BCE roughly delineates the Neolithic phase of Jomon culture, some evidence implies that Jomon peoples inhabited the Japanese archipelago perhaps before 16,500 BCE.

By 10,000 BCE, the Jomon seashore cave encampments and pit-house settlements along river tributaries were numerous. Pit-house villages were seasonally occupied so that the Jomon could engage in horticulture during summer, when they also fished with nets and bone hooks (fiber lines, stone sinkers), foraged with digging sticks for various tubers, and collected wild nuts and plants. They also hunted deer and boar with bows and traps during the winter months. Technology included ground stone artifacts such as arrow and spear heads, a stone device used to straighten arrow shafts, stone grinders and querns for processing nuts and berries, clothing (rope made of plant fibers also used for cloth), and the manufacture of pottery and clay figurines. Part of their diet consisted of fish obtainable only in deep seawater, suggesting the use of watercraft as well as the possibility of long-distance trade.

vessels gouged out of stone were heavy and for that reason were not easily portable. The chief drawback, however, is that natural fibers and skins are combustible. Even stones crack when subjected to fire. Therefore, the invention of unfired clay pottery (much lighter than stone) followed by fired clay pottery (ceramics that could store liquids and better resist fire) were technological advancements. Fire does not destroy clay pottery but rather renders it stronger, harder, and less permeable than unfired clay pottery;

therefore, it is more suitable for the storage of liquids and for cooking.

The preceramic Neolithic Age was of long duration, and many factors determined subsequent developments. Knowledge of the physical properties of the various sorts of clay, its chemical reaction during exposure to the sun's rays and fire, and the effects of adding “openers” (also referred to as “tempers”) such as sand, small fragments of flint or lime, crushed shells, chopped grass, cinders, dried dung, or crushed pottery (termed “grog”) in order to improve clay that is malleable but that retains too much water were all such empirical observations necessary to the development of ceramic manufacture.

The following brief description of the most ancient methods of pottery production combines archaeological evidence coupled with data from specific societies that preserve ancient pottery traditions through ethnoarchaeology to provide the researcher with insights into the practicalities and technology of pottery manufacture. First, suitable clays were dug from the earth's surface and washed clean of loose soil and foreign particles such as large stones. The clay was then mixed with water to achieve a specific consistency, squeezing it by hand or pressing it beneath the feet. Finally, the clay was shaped into a pot, bowl, drinking vessel, or figurine.

For small bowls the clay may have been first gathered into a lump of clay or ball. A fist then punched a deep hole into the ball, and the hole was enlarged by degrees, while the walls of the vessel were molded by hand. With larger pots the fist technique may have been used for the initial lump of clay, but the potter then built up the walls of the vessel a little at a time with subsequent additions of handfuls of clay around the insides of the pot, pressing ever outwardly in order to gradually enlarge the vessel's cavity until the desired holding capacity was attained. Sometimes a basket served as the mold, and a thick layer of clay was smeared over it or inside of it. Sometimes an inverted pot served the same purpose. The mold removed, the pot was then smoothed both inside and out by means of scrapers and then with a handheld piece of leather.

A second ancient method of pottery manufacture was to coil ropes of pliant clay upon a base of clay, working the coils together in such a

way that they were no longer discernable. Scrapers and a piece of leather smoothed both the inside of the vessel and its outer surface. Decoration was sometimes added by making incisions with a sharp object; sometimes rope or matting was pressed into the wet clay. The pot was then set in the sun to dry. Items that are merely sunbaked, however, are only suitable for holding dry goods. Unfired clay pottery absorbs liquid, which eventually destroys it. Fired clay pottery, in contrast, is much less permeable, for clay contains a percentage of so-called free water—that is, water that evaporates as the pot dries in the sun and air currents—but it also contains “combined” water, which can only be extracted from the clay at temperatures from 650–750 degrees Fahrenheit (350–400 degrees Celsius) and above which completely alters its chemical composition. It can never be returned to plasticity again, yet the pot will more easily hold liquids, and it is sufficiently strong and hard enough to place it in proximity to a cooking fire. The chemical composition of the clay and its method of firing will determine the color of the finished product.

The earliest method of firing pottery is to sun-dry it for a short amount of time at first and then to place it in contact with fire. However, the hotter the fire, the harder and the more impermeable the vessel becomes. Potters after 7650 BCE invented ways to make vessels impermeable in two ways. They discovered that very fine clay could be mixed with water to form “slips,” which were then smeared over the pot and fired for greater impermeability. They also learned to subject clay vessels to very high temperatures and to sustain high temperatures by means of ovens.

The first oven seems to have been a hole dug in the ground, the floor of the shallow hole being made sufficiently flat and large enough to accommodate a number of vessels whose rims did not protrude above the surface of the ground. The pots were then surrounded and covered in a mound of charcoal, wood kindling was heaped around and over the mound, and the entire structure was ignited. Air passages cut at a diagonal through the ground to the level where the pots rested would allow bellows to force air into the hole, thus creating and sustaining very high temperatures. Toward the end of the Neolithic (roughly 6000–4000 BCE) aboveground ovens

➤ EARLY SAHARAN CERAMICS

The earliest ceramics in North Africa predate those from the Near East by two millennia. They have traditionally been ascribed to two groups: dotted wavy line and wavy line.

The wavy-line pottery originated in the Nile Valley, from the tenth millennium BCE onward, and is most prevalent in the central Nile. Six subtypes have been recognized: classic waves, angular waves, mild waves, arched waves, serpentine waves, and composite motif. It was originally excavated, described, and (poorly) defined by Arkell in the mid-twentieth century.

Some of the motifs allotted to the wavy-line pottery are lacking wavy lines. The wavy-line motifs were produced by catfish spines, which were used to produce other motifs as well. Thus, implements, techniques, and motifs were originally conflated.

True Saharan wavy-line pottery occurs as scattered sherds, ill-provenanced and of debatable dating. It was relatively slow in diffusing into the Sahara and reflects a limited distribution.

By contrast, dotted wavy-line pottery originated in the Sahara. It was present from the tenth millennium onward and probably spread quickly to the Nile Valley through exogamy and/or trade exchange. There are three types of discernable motifs: deep dotted waves, shallow dotted waves, and angular dotted waves.

Both the wavy-line and dotted wavy-line pottery were made from locally derived materials. The matrix and temper are a strong argument against the pottery being representative of a homogeneous cultural complex, such as Camps-Fabrer's Saharan Sudanese Complex. The pottery cannot be considered forms to determine diagnostic cultural traits, but they hold potential for analyzing cultural variations and covariations within and between regions.

—Michael Brass

were built of clay, and finally enclosed ovens, or clay “kilns,” made the extremely high temperatures necessary for both high-quality ceramics manufacture and the smelting of metals.

We gain a better understanding of the chronological development of ceramic manufacture by examining data from excavations at a particular site (Tell Maghzaliyah) just west and south of

the Tigris River in Iraqi Kurdistan. Artifacts and architectural features from the lowest level of this site yield dates of approximately 7000 to 6000 BCE and may therefore represent a connection between aceramic culture and that of the ceramic, for its inhabitants suggest that they were close to developing ceramic vessels.

One architectural tradition at Meghzaliyah was to make floors of stone slabs that were then smoothed over with clay and covered with a plaster. The inside walls were also plastered, attesting to growing knowledge of the chemical properties of clay. As to the domestication of fire, unfired clay storage bins for grain coexist with clay ovens for baking bread. A piece of bitumen having reed mat impressions suggests that basketry still was being made impermeable with applications of various sorts of resins and tars and that pottery yet could not store liquids for any length of time. Stone vessels of sophisticated manufacture predominate at the site of Meghzaliyah, yet unfired clay artifacts (pottery, ovens, and dwelling places) are numerous, as are lumps of kneaded unfired clay. Also found at the site were many fragments of unfired clay figurines of women. In 1980 two nearly complete figurines were uncovered. They are both seated and have disproportionately large torsos resembling an “elongated cone” that has “small” protrusions to suggest breasts.

The site of Tell Sotto just southeast of Maghzaliyah, dated sometime after 5000 BCE, revealed ceramic storage jars, clay and stone spindles, clay pellets for slings, clay ovens, and clay pottery that had been tempered with organic material and shells or sand and then fired. There was also red and black burnished thin-walled fired pottery. Some of it was decorated with zoomorphic and anthropomorphic figures molded of clay and attached to the rims of the vessels. At the nearby site of Yarim Tepe I (approximately 5000–4000 BCE) were found 13 domed kilns constructed of clay located outside of the dwelling places, indicating that technological advances had reached that of the ceramic stage.

Mining and Metallurgy, 10,000–4000 BCE

With the advent of the Neolithic, humans began to selectively breed animals and to plant cereal crops, becoming semisedentary pastoralists, or sedentary farmers. This transformation in the subsistence economy freed Neolithic people from having to hunt wild game or gather wild foodstuffs, permitting some people to pursue specialized crafts. Artisans learned to grind and polish stone, revealing its brilliant colorations and metallic content.

Between 5400 and 4000 BCE (the Chalcolithic Age), humans learned the properties of copper, and Old Stone Age (Paleolithic) technologies merged with those of the New Stone Age. However, adherence to a strict chronology is problematic for copper technologies developed at different times at various places of the globe. The oldest finds of copper artifacts are located in the Middle East dated to between 7000 and 4000 BCE, in the Nile Valley between 6000 and 3500 BCE, but in the Mediterranean and Europe not until after 3500 BCE, which puts these areas beyond the purview of this article.

Gold and copper seem to have been the first metals to have attracted the attention of early Neolithic artisans because “native” gold and copper occur “freely” in nature, that is, as simple metals, not as chemical compounds, and may be found on the surface of the earth in mountainous regions, riverbeds, and streams. Because gold does not corrode or tarnish, shiny nuggets of it were readily discernable to the human eye, whereas the surface of copper oxidizes to a greenish hue and must be polished to reveal its

slightly reddish luster. For this reason, the desirable properties of copper were probably discovered after those of gold. Large and small gold nuggets were first made into beads by grinding to size and polishing them, and they were then strung to form necklaces and bracelets. Gold may also have been hammered into sheets that could then be cut into various shapes and sizes, and its malleability (softness) allowed it to be rolled and twisted into wire. Yet its very softness made it unsuitable for weaponry or cutting tools. The Late Neolithic cemetery at Varna in Bulgaria dated from 4500 to 4000 BCE yielded a stone ax with a gold decorated haft, gold face ornaments, a gold penis sheathe, and an ax covered in sheet gold.

Copper artifacts also date to Early Neolithic times. Copper beads found at the site of Çatalhöyük in Turkey date from between 7000 and 6000 BCE. A copper mace from the Ur excavations in Iraq dates to between 5000 and 4000 BCE. Copper was shaped by grinding nuggets down to size and polishing them or by hammering them into flattened sheets cut to form awls, pins, fishhooks, and spearheads. However, copper is rather brittle and, if beaten for too long, cracks. Prior to 5000 BCE artisans discovered that if copper was heated (annealed) in a wood fire and subsequently hammered, not only was it more easily shaped, it also became twice as hard, making it much more suitable for cutting tools and weaponry. Stone tools wear out more quickly than those made of copper. Copper weapons are lighter in weight and therefore more easily handled. The mining of metals does not seem to have occurred until after 4000 BCE, nor smelting (the extraction of metals from rock), nor the use of casts; these developments occurring after 4000 BCE.

The invention of pottery led to metallurgical advances. To produce fine ceramics, knowledge of chemistry is necessary, and the firing of ceramics cannot be accomplished without pottery kilns (ovens). Closed ovens that could attain extremely high temperatures facilitated the making of ceramic pottery, fired bricks, and the smelting and the casting of metals. This took place after 4000 BCE.

Archaeologists are not in total agreement regarding early metal use. The above-mentioned

dates are disputed among scholars. Archaeologists also debate whether knowledge of metallurgy spread from the Middle East to Europe or whether metallurgy developed independently in various regions. One ubiquitous contention concerns the identity and subsistence economy of the people who first learned how to work metal. It is now believed that Neolithic farmers most probably were not the people who prospected for metal or made artifacts of it for the simple reason that Neolithic farming settlements were generally located in the major river valleys, whereas metals, even native gold and copper, are most often found in the mountainous regions of the earth. Furthermore, people who trade and work in metals are of necessity nomadic. The search for metals requires travel to those mountainous regions where they are plentiful. The need for timber in annealing and later in smelting metals was great, and the depletion of timber was rapid in the heavily populated river valleys where agriculture had first developed, whereas the remote mountain ranges are often heavily wooded.

More probably, Neolithic farmers traded their surplus food for metal objects made by full-time specialists living and working where metals and timber were plentiful. Metalworking may be one of the oldest of the specialist crafts except that of the magician. Indeed, metalworkers were regarded as magicians from ancient times and are still regarded as such among shamanistic peoples even today. There is also evidence that miners and smiths comprised separate castes that intermarried only with one another and whose knowledge of geology, chemistry, and physics was kept secret, being transmitted genealogically from parents to children. For this reason, metalworkers all over the world were feared and regarded with awe by the various peasant populations. Recently, archaeologists have collaborated with the cultural anthropologists who have researched contemporary metalworking castes and tribal peoples of Asia and Africa for

Copper mace heads, from the Cave of the Treasure (Nahal Mishmar) in the Judean Desert, Chalcolithic, 4500–3500 BCE. (Erich Lessing/Art Resource, NY)

insights into the metallurgical past. For example, the metalworking Ghorbati of southern Iran are nomads. They transmit metallurgical secrets orally from elders to the younger generation, and sedentary populations regard them as magicians and witches.

The Emergence of Watercraft and Its Social Implications, 10,000–4000 BCE

The invention of watercraft and its chronology, technology, and world distribution have widespread social implications. Watercraft allowed human populations to explore oceans, thereby permitting human expansion to previously uninhabited island archipelagos around the world and the discovery in the process of fresh stores of aquatic food supplies only accessible from deep seawaters. In addition, watercraft allowed the charting of rivers and their tributaries that led to previously unknown territories, facilitating the discovery of raw materials and land for the production of culture. The invention of watercraft also changed the length of time required for long-distance trading. Travel by means of boats, even mere rafts for the transportation of people, animals, foodstuffs, and other products of human labor, is much more rapid than overland travel. New research suggests that as a result of the harvesting of aquatic resources and the expansion of long-distance trading by means of seas and waterways, a unique way of life developed based upon ancient boat-building technologies that were sometimes orally transmitted from one generation to the next.

Regarding the invention of watercraft, the archaeological record is far from conclusive;

therefore, it is a matter of contention among archaeologists today. The major reason for various interpretations of the archaeological record is that actual specimens of vessels are scant. For example, rather than actual boats, some of the earliest evidence is of miniature models depicting watercraft constructed of papyrus bundles uncovered at archaeological sites in Egypt dating from between 6000 and 5000 BCE. Regarding watercraft made of bundled reeds (a very ancient form of boat construction), archaeologists formerly thought them to be unseaworthy and suitable only for river travel. However, explorer and writer Thor Heyerdahl proved that various reed-constructed boats were seaworthy in 1977 when he sailed his reed boat, “Tigris,” through the Persian Gulf from Iraq across the Arabian Sea to Karachi, India, and then back again to Djibouti at the mouth of the Red Sea.

Archaeologists cannot be certain as to whether papyrus and reed-bundle construction was followed by wooden plank construction of watercraft or if they developed simultaneously, but between 5500 and 3500 BCE Egyptian boats began to be built of wooden planks either lashed (“sewn”) together or joined by means of mortise and tenon. Egyptian mortuary practices also included the burying of full-sized boats with the dead sometime between 4000 and 3000 BCE. One such boat of cedar planks was found buried in a pit near the pyramid of Giza, dated to between 4500 and 3500 BCE. Clearly, the boat had social and ritual significance for the Egyptians, although archaeologists are not certain as to its exact nature.

There is further evidence for the existence of watercraft in Mesopotamia, along the Tigris and the Euphrates rivers and their tributaries. At certain sites of the Ubaid period between 5000 and 3800 BCE, clay models of ships of wooden plank construction were discovered.

Also found were the remains of small watercraft at European sites. Three complete wooden boats (dated to between 6000 and 5000 BCE) were found at Mecklenburg in northern Germany on the Baltic coast. However, at times archaeologists have had to infer the presence of watercraft from the presence of other artifacts such as a birch-wood paddle preserved in peat bog excavated at Star Carr in northern England

that is dated to approximately 6000 to 5000 BCE. From this paddle, archaeologists postulate the existence of a boat that was constructed either of sewn skins or birch bark stretched over a wooden frame. Another possibility is that the boat may have been constructed of bundled marsh reeds. However, no such boat was ever found at the site because of the perishable character of skins, birch bark, and reeds. And although small watercraft such as dugout log canoes and boats of wooden plank construction can be well preserved especially in water-saturated soils and peat bogs, no wooden frame was located either.

The existence of watercraft is also hypothesized from the bones of fish and other aquatic life only attainable from deep seawaters, such as those found discarded at Neolithic campsites along the seacoasts of Europe, the Middle East, and Asia. Of equal significance but few in number are fragments of bitumen found to have reed or wood impressions in them, the other side being encrusted with barnacles. Bitumen was used to caulk watercraft, thus making it impervious to water. Such fragments were found at many Neolithic sites (7000–3500 BCE). Other artifacts that suggest use of some sort of watercraft are nets made of plant fibers, fishing hooks made of bone, fishing lines made of plant fiber, and stone sinkers. However, one must also bear in mind that fishing is possible from the banks of rivers and in the shallows of a bay, in which case the watercraft might have been as simple as a raft of reeds or of wooden planks lashed together with sinew or strong rope made of plant fibers. One problematic issue faced by archaeologists was articulated by historian Himanshu Prahba Ray in that studies of the Neolithic era (10,000–4000 BCE) have generally focused upon the domestication of land plants and land animals as well as overland trade routes, thus causing a paucity of information about marine life exploitation by early *Homo sapiens* and the development of concurrent ichthyology.

THE DUFUNA DUGOUT

One of the oldest means of transportation by humans is the use of boats. Boats were used effectively over the ages by humans for the exploitation of aquatic resources and for rapid communication between communities over long distances. In Africa this type of activity has been ongoing for a long period of time. Evidence for this assertion comes from Dufuna, which is located between Potiskum and Gashua in northern Nigeria. At this site a canoe was discovered dating to 5500 BCE in a fully preserved state. It was the first of its kind to be discovered in sub-Saharan Africa. It has a length of 27.5 feet (8.40 meters) and a maximum breadth and height of 1.6 feet (0.5 meters), while the sides were about 2 inches (5 centimeters) thick. African mahogany (*Khaya senegalensis*) was used for the construction of the boat. This specific species used has a widespread distribution all over the savanna region of Africa. It has been suggested that the Dufuna canoe would have been used for the exploitation of the fish stocks of the Komadugu Gana River. It has also been postulated that the boat might have existed at a time when the surface level of the Chad was about 130 feet (40 meters) higher than its present level, a period generally referred to as the Mega-Chad.

Early Farming and Agricultural Technologies

Humans, including our earliest ancestors, have consumed plants for millions of years. However, it has only been within the past 12,000 years that humans have cultivated and then domesticated plants for their subsistence. Over time, humans created a wide range of technologies to clear land, plant seeds, manage water, harvest crops, and then store them for future use. Some technologies were more subtle and involved manipulating the plants themselves in an effort to

create larger seeds or more robust varieties resistant to cold or drought.

Although hunters and gatherers in many parts of the world included plants in their diet, the technologies used to obtain them probably remained stable for much of human history. Such tools as grinding stones were used to process seeds that were harvested. Digging sticks may have been used to excavate tubers or underground roots, and cutting tools may have been used to cut stalks.

As humans became more reliant upon plants, technologies began to change, and more specialized tools, allocations of labor, and perceptions of the landscape began to appear. Specialized plant-processing tools are first seen in the ancient Near East in the Levant, where grinding stones suitable for processing hard seeds begin to appear in abundance after 20,000 years ago. Mortars and pestles are found to appear more frequently as well. Although these are not direct indicators of cultivation or agriculture, they signal a more intensive use of plants that prefigures, in many parts of the world, eventual domestication of plant species.

In the Natufian culture of the Levant, dated between 12,000 and 9600 BCE, lunate-shaped chipped stone blades make their first appearance. Although similar microlithic tools are known from earlier periods in the region, these tools appear to be sickle blades, and those that have been examined in detail provide some evidence of being used to cut plants. The blades were probably set in a wooden or bone haft. Their standardized shape and limited range of functions is indicative of their specialized use. Most archaeologists believe that the appearance of these tools signals an even more intense reliance upon plants than in previous periods.

In all likelihood, Natufian peoples were engaged in the cultivation of the wild plants of the region. Cultivation involves the clearing and planting of fields, weeding and care of the plants while growing, and, of course, harvesting when ripe. Although people may be heavily reliant upon these plants, cultivation is not the same as domestication, which is best seen as a significant transformation of the biology and genetics of the plant, making it ultimately dependent upon hu-

man intervention for its reproduction. As these groups find themselves even more reliant upon these modified plants, major changes in how labor is deployed and how landscapes are used can be observed, and for most archaeologists this signals the appearance of agriculture, which is best seen as a major transformation of the relationship among humans, domesticated species, and their environments.

It is relatively easy to see domesticated plants in the archaeological record. For example, seeds of domesticated plants are larger than their wild ancestors, and some plant structures, such as the heads that hold the seeds, change from a brittle form to one that can withstand being cut or shaken. Finding direct evidence of new technologies, changes in labor, or landscape modifications, however, is more difficult. In fact, the results of the reliance upon agricultural production—such as growth in population, appearance of larger towns, and greater political complexity—are more evident to the archaeologist than are the technologies that led to such outcomes.

Sometimes settlement location provides an indirect means by which to infer the existence of an agricultural technology. The earliest farming villages in Mesopotamia, for example, were located on terraces above river valleys. This suggests that the farmers were dependent upon rainfall. Over time, however, these settlements moved on the valley floors themselves, and this suggests reliance on a different kind of water-control strategy, one based on simple irrigation systems composed of networks of small canals that brought water from the river to the fields. Such small-scale irrigation systems became far more common in this region after 6000 BCE.

But the creation of specialized agricultural technologies does not always lead to increased social complexity. Instead, it may be a response to unusual environmental conditions. Such is the case with evidence for early plant cultivation in highland New Guinea, particularly at Kuk. Archaeologists have discovered evidence for forest clearance as early as 7000 BCE and mounding of soil by 5000 BCE. More elaborate systems of drainage canals and ditches did not appear until much later, around 2000 BCE. Here, the mounding of the soil was likely under-

taken to get plants above the soggy soil so that roots would not rot.

In most regions, the soil was tilled or turned with spades made of animal bones (especially the scapula, or shoulder bone), wood, or stone and with digging sticks. Stone spades have been found in China at the Cishan site, which dates to circa 6000 BCE, and bone spades have been recovered from other Chinese Neolithic sites. Such tools were likely common throughout much of the ancient Near East and Europe during the Neolithic period. Because they rely exclusively upon human labor, these types of agricultural tools mean that field sizes were relatively small.

The domestication of cattle and then the invention of the plow transformed agricultural practice throughout much of the Old World. Although cattle had been domesticated in the Near East as early as 8000 BCE, there is little evidence of their use in agriculture until circa 5000 BCE. Early plows were made of wood; evidence for the use of the plow comes from furrows or plow marks in ancient fields. Plows entered eastern Europe by 4500 BCE, and by 4000 BCE they were found throughout much of western Europe as well. The advantage of the plow over spades or digging sticks is that the plow is much more efficient. More land can be tilled with the same amount of labor. It is likely that the combination of plow and animal traction was a response to

increasing population growth throughout the Neolithic.

An overlooked technology is one that humans developed as they began to move agricultural technologies into more forested regions, so-called slash-and-burn agriculture. Before the invention of metal tools, stone tools (but also sometimes bone tools) were used to cut trees. These axes, often made of polished hard stone, were of limited effectiveness when confronted with large, thick hardwood trees. To clear land for fields, then, people turned to the use of fire combined with the girdling of trees, cutting through the soft area just below the bark that is responsible for moving nutrients through the tree. Smaller trees and brush could either be cut or burned. This technique, still used today, had the added advantage of adding essential nutrients to the soil through the ash from the burned wood. This method of land clearance was used during much of the expansion of agriculture into Europe as well as East Asia.

ERA 2 Early Civilizations, 4000–1000 BCE

The story of Gilgamesh, the semilegendary king of Uruk in Mesopotamia (present-day Iraq), deals with themes such as coping with grief and understanding the meaning of life and death, which are as relevant to modern life as they were to life 5,000 years ago. Gilgamesh, saddened by the death of his friend Enkidu, went on a quest for eternal life, a quest that ends in failure. At the end of the story, Gilgamesh comes to the realization that nothing lasts forever, stating that “Nobody hears the voice of death, brutal death cuts mankind down,” and resigns himself to the fate that awaits everyone. Yet we are still reading about Gilgamesh’s exploits today and exploring the ancient houses of Uruk through archaeology. The *Epic of Gilgamesh* (in its various incarnations) stands as a monument to human creativity and cultural achievement.

The developments in writing and literature, art and architecture, science and discovery, and politics and governance that took place during this 3,000-year period have been foundational in world history. Perhaps these manifestations of human ingenuity best capture the spirit of this era or at the very least capture what has been important to modern historians about this era. The *Epic of Gilgamesh* is not the only piece of literature to have been produced in this era noteworthy for world historians. While the Mesopotamians and Egyptians were perhaps the most prolific, the original oral compositions that eventually became the Homeric epics from Greece, the Vedas of India, and parts of the Tanakh (the Hebrew Bible, or so-called Old Testament) likely originated in this era. The world’s first named author dates to this period: Enheduanna, a woman from Ur (in Mesopotamia).

This is the period of the Great Pyramid of Giza in Egypt and Stonehenge on the Salisbury Plain in England, two monuments that have captured the imagination since their construction. This is a period of artistic fluorescence in many media, from the elaborate Shang bronzes of China to the whimsical frescoes of the Minoan palaces. Scientific theorizing and observation begin in a recognizable form; some branches, such as zoology and botany, are still practiced as science today, while others, such as astrology, have been relegated to pseudoscience. Most of us do not even question the existence of the state as a form of governance. 4000 to 1000 BCE is the period of the first states as well as the first kings (although probably not the first taxes, which apparently originated farther back in the past). In this period, people started to specialize in their work. Some were able to engage in work that went beyond simply providing food,

4000 to 1000 BCE is the period of the first states as well as the first kings (although probably not the first taxes, which apparently originated further back in the past).

shelter, and clothing, even if basic subsistence remained the most important goal for most of the population.

How Do We Know What We Know?

Given the number of firsts achieved between 4000 BCE and 1000 BCE, it is shocking how much has been forgotten. Most of what we know about this time period was rediscovered in the past 300 years through archaeology and related disciplines. Any historical work in this time period is dependent on archaeology. Most of the texts that date to this period have been recovered through archaeology. Many of these ancient languages were forgotten and have had to be relearned, whereas others remain indecipherable. Knowledge of these civilizations was mostly lost, replaced by hazy traditions and legends that surrounded the monuments that still remained aboveground. Over time, people rebuilt in the same places: knocked down older buildings, leveled the ground, and built atop the ruins. In some cases, the cities were utterly destroyed, the regions abandoned or the inhabitants killed off, and the ruins were left to be buried by natural processes. So, to find out about these cultures, we needed to excavate first. Even scholars who only work with ancient texts are reliant on archaeologists to dig up the texts.

With the birth of writing in this period comes the birth of history. Not that the lives of people that preceded this period are any less important; rather, writing led to the production of the historian's most important type of evidence: written documents. For all of their flaws and inadequacies, such as usually being written by and for elites, the preserved writings of ancient peoples allow the modern historian far greater access to the details of individual lives than any other source, even archaeology. The information that historians have access to exists on a far larger scale for literate societies than for those without writing.

The same problem is apparent when we compare the treatment of different regions within this period. The Egyptians and the Mesopotamians wrote in a script that we can read today on materials that survive archaeologically, so we know far more about them than we do about the inhabitants of the Indus Valley in India, who had a type of writing that, however, exists only in fragments and is still indecipherable. The Mesopotamians wrote on clay, which can survive for thousands of years when fired and buried, by purpose or chance. The Egyptians wrote on papyrus, which has lasted well in the arid Egyptian climate, and on the faces of their architecture, which was built of stone and has lasted for thousands of years. The people who lived between Egypt and Mesopotamia, in the region called Syria-Palestine, wrote on both clay and papyrus. There the clay tablets have survived, but the moist climate has destroyed most papyrus, so our record is further skewed. The ancient Chinese wrote on a variety of materials including bones and tortoise shells, which survive archaeologically, but other organic materials (if they were used in China during this era) have not lasted. The earliest writing in the Americas may be an Olmec inscription dating to 900 BCE (called the Cascajal Block), but this requires further analysis.

Archaeological remains are no different in this sense. The more that people built, the more likely modern scholars are to find the ruins. As noted, the Egyptians built in stone and on such a massive scale that many of their buildings were never lost. The Mesopotamians and the inhabitants of the Indus Valley built in mud brick, which is easily knocked over, but these crumbled and buried remains preserve relatively well until they are exposed and disturbed by erosional processes. The cultures of South America and Mesoamerica built great stone edifices that have survived the hot and humid climate. The inhabitants of North America during this time, however, built homes and tools mostly in organic materials; since these materials do not survive well in the North American climate, our knowledge of these people is similarly fragmented at best. This is the frustrating part of studying the people of this period: we are limited to what has been accidentally preserved and then uncovered archaeologically.

Our knowledge of the ancient past is limited not only by the ravages of passing time but also by the ravages of current events. Modern political boundaries and ideological debates threaten historians' ability to do their work or share their findings with their colleagues. To do their work, they have to be able to visit the locations where these people lived, conduct archaeological excavations in these regions, study the artifacts in local and national museums, and read ancient texts in the universities that are charged with conserving them. Armed conflict is very damaging to the study of ancient world history. Right now, the Mesopotamian heritage is in real danger because of the political situation in Iraq. When American- and British-led forces invaded Iraq, there was no plan in place to care for the antiquities, as mandated by the Geneva Conventions. The looting of the Baghdad Museum was the first sign that Iraq's ancient past was threatened. The situation has become far worse due to American and British forces damaging artifacts and archaeological sites, insurgent attacks, growing ideological opposition to the study of ancient Mesopotamia, and looters illegally excavating Iraqi artifacts to sell to European and American collectors on the black market. The problem in Iraq shows how quickly the situation can change for historians. Mesopotamia, which was once one of the most studied regions in this period, may become one of the least studied regions.

Egypt and Africa

We will start our exploration of this era with the region that is paradoxically both the most and least studied of this period: Africa. Far and away, we have the most evidence for ancient Egypt. At the same time, the rest of Africa from 4000 to 1000 BCE has stood in the shadow of Egypt. Other African cultures have long been treated as footnotes to Egypt, even though cultures such as that of the Nubians (located in modern-day Sudan) are much in evidence. This tendency is changing, but at present most of our knowledge of African life for the period from 4000 to 1000 BCE centers on Egypt.

The first stirrings of an Egyptian state appeared sometime between 3200 and 3000 BCE. Prior to this, in what scholars call the Naqada period (4000 to 3000 BCE), the land of Egypt was divided roughly into two distinct culture zones. The north (or Lower Egypt, because the Nile flows north) and the south (or Upper Egypt) had different material cultures from one another, which is not surprising given the very different climates in the two regions. Between 3200 and 3000 BCE these two regions became unified (although the exact process of unification is debated by scholars), forming the state of Egypt. However, the existence of two conceptually separate regions within Egypt continued to be reflected in Egyptian political iconography, and tensions between the two regions flared up periodically.

Nubia was of great interest to the ancient Egyptians. It held desirable resources (especially gold and labor power), and it held potential danger to the Egyptian state, as a potential rival in times of Nubian power.

The story in the rest of Africa is not as clear. We know about the kingdom of Nubia (located in what is now known as Sudan, south of Egypt) mostly through Egyptian records and the limited archaeological excavations. Nubia was of great interest to the ancient Egyptians. It held desirable resources (especially gold and labor power), and it held potential danger to the Egyptian state, as a potential rival in times of Nubian power. Thus, historians who are interested in Nubia have a lot of evidence to work with in this time period, but most of that evidence comes from an Egyptian perspective. Many other parts of Africa came into contact with the Egyptians who sought resources throughout the northeastern part of the continent.

Archaeology in the rest of Africa has not been as fruitful, although there have been significant finds in recent years. During this time, people inhabited both the savannas and the forests of Africa. Pastoralism and hunting and gathering were the most common means of subsistence. Yet sometime between 4000 and 1000 BCE, agriculture took root in Africa; some of the crops, such as millet, that are grown in Africa today were first cultivated at this time. Beyond subsistence practices, we are on less sure footing in our understanding of Africa. Remains of cultural practices (such as the Saharan rock carvings of Tassili n' Ajjer in present-day southeastern Algeria) tantalize archaeologists, hinting at a rich heritage that remains to be discovered by scholars. Ethiopian archaeology has also demonstrated that there was increasing social complexity in the northeastern Horn of Africa throughout this period. Likewise, archaeological and linguistic evidence suggests that the origins of the Bantu migration (a centuries-long movement of Bantu speakers throughout Africa) were prior to 1000 BCE.

Mesopotamia and the Near East

Mesopotamia, in what is now known as Iraq (and parts of Syria and Turkey), rivaled Egypt as a regional power. Contact between the regions existed from at least the very beginning of this period. The clearest evi-

dence for this contact comes in the form of shared artistic motifs (such as images of humans mastering animals) and shared material culture (such as cylinder seals and certain types of pottery forms). Egyptologists and Sumerologists (scholars who study Sumerian, the earliest written Mesopotamian language) argue over who invented writing first and whether one region learned of it from the other.

Unlike Egypt, Mesopotamia was rarely a fully unified political state. The name itself is a later Greek term that translates as “the land between two rivers.” The two rivers are the Tigris and Euphrates, and generally when scholars talk about Mesopotamia, they refer to the cultures centered between these two rivers. While the people who lived in ancient Iraq frequently lived in a politically fragmented area, there were considerable social and cultural practices that united them. Scholars sometimes refer to these shared practices as the cuneiform tradition, a tradition that spanned beyond Mesopotamia proper and extends throughout the ancient Near East. Cuneiform (meaning “wedge-shaped”) is the type of writing that was used in this region. The name refers to the shape of the letters, created by a scribe impressing a reed stylus into clay tablets. Cuneiform was used for a number of different languages including Sumerian, Akkadian, Ugaritic, and Hittite, not all of which were Mesopotamian. There was much similarity among the cultures that used cuneiform. Even when they did not share the same language, they shared legal and diplomatic traditions as well as social practices. In some ways, cuneiform connected the Near East, Africa, and the eastern Mediterranean in a system of mutually understood customs and ideas.

Scholars of ancient Mesopotamia further subdivide it by time period and region. The most important division for the ancients themselves was between the north and south. In the earliest periods, scholars refer to the southern people as Sumerians (speakers of Sumerian) and use the general designation of Sumer to refer to this culture, although Sumer was never a fully realized political state, as was Egypt; Sumer is best thought of as a group of competing city-states. Toward the end of this period, this southern region came to be known as Babylonia because of the prominence of the ancient city of Babylon. In older works, scholars would sometimes refer to this region as the Chaldees because this is often how it is referred to in early biblical texts. However, the scholarship of the past 200 years has shown that this is an inappropriate designation for Babylonia, since the name “Chaldees” is derived from a group of people who emerged in the region in a later period, in the period of the Neo-Babylonian dynasty. The situation in the north in the early periods is less straightforward. By about 2000 BCE, scholars can safely refer to the north as Assyria. Most scholars of Mesopotamia refer to themselves as Assyriologists, but this is just a convention; it does not mean that they limit themselves to the study of ancient Assyria.

Given the close proximity of Anatolia (present-day Asian Turkey) to Mesopotamia (present-day Iraq), it is no surprise that the people of these two regions were in frequent contact with one another. Much of what we know about these cultures comes from Mesopotamian and Egyptian sources, and often this information is confused (or confusing). For example, the state of Mittani (located in what is now southern

Turkey and northern Syria) was very important in the late second millennium. A lot of information about this state is found in cities located on its periphery. From these sources we can glean much about its political and social history. We know that the capital was a city named Washukanni, but we do not know exactly where that city was. We know that the Hittites called it “the land of the Hurrians.” We know the Hurrians were a much older group from this region with a distinct language that was widely spoken, but we have only relatively few texts written in it. On the other hand, modern scholars know a significant amount about the Hittites, who were located in the central region of Anatolia during much of the second millennium. They spoke an Indo-European language (which is markedly different from the rest of the ancient Near East, where Semitic languages were predominant).

Between Egypt and Mesopotamia-Anatolia lies the region scholars call Syria-Palestine, or the Levant (where the modern political entities

of Israel, Syria, Palestine, Jordan, and Lebanon now lie). When we think of this region today, we cannot help but imagine dry, dusty deserts empty of vegetation and difficult for people to survive in. This region, however, was one of the richest areas on earth in terms of natural resources. The biblical description of this region as a “land of milk and honey” was not an exaggeration. The temperate climate and productive soil and the fact that the Levant provided the only land route between Af-

The biblical description of this region as a “land of milk and honey” was not an exaggeration. The temperate climate and productive soil and the fact that the Levant provided the only land route between Africa and Asia meant that this region was heavily contested.

rica and Asia meant that this region was heavily contested. Much of the history of the Levant in this period centers on the struggles between the larger powers that surrounded it, struggles that played out in Syria-Palestine. For much of this period, Egypt held sway over the region. The local governments were small city-states whose power waxed and waned relative to Egypt’s authority or the shifting powers in Anatolia.

Despite (or because of) this, the Levant from 4000 BCE to 1000 BCE is of great importance in world history. It is here that the alphabet rose to prominence as a writing system, over the more complex hieroglyphic and cuneiform systems. It is also the center of much of the narrative of the Tanakh (Old Testament). While only a handful of passages from the Tanakh were actually written during this time, much of the Tanakh centers on events that were supposed to have occurred in this period. While the historicity of the Bible is heavily debated by scholars, these traditions about this time period play an important role in the beliefs of Jews, Christians, and Muslims today.

Greece and the Mediterranean World

Throughout the period from 4000 to 1000 BCE there was significant interaction among the Near Eastern cultures and the people of ancient Greece. The shared Mediterranean Sea provided relatively easy trans-

portation; the shared climate meant that there were many cultural similarities between these areas. The extent of interaction is fiercely debated by scholars; usually the interaction is underemphasized since scholars are trained in either Greek archaeology or Near Eastern archaeology but not usually both. Regardless of how intense the interaction was, the Mediterranean indirectly linked much of Southern Europe with the Near East and Egypt.

During the Bronze Age, Minoan civilization emerged on the island of Crete. The Minoans left behind monumental palaces, elaborate pottery, and a yet to be deciphered script, Linear A. Perhaps most impressive are the frescoes that the Minoans left behind. Painted directly onto the wet plaster of the walls of Minoan buildings, these frescoes provide us access to a unique visual culture. Minoan men and women leaping over bulls, Minoan women parading in elaborate gowns, and dolphins and monkeys frolicking in idyllic settings attest to a rich artistic aesthetic. What this aesthetic reflects about Minoan society is difficult to determine. Minoan civilization came to an end under uncertain circumstances. A volcano erupted on the nearby island of Thera (present-day Santorini) around this time, although the exact date and effects of the eruption are heavily debated. Perhaps this culture was conquered by the more warfare-prone Mycenaean Greeks who inhabited Crete after the Minoans. Whatever the case may be, Minoan civilization came to an end.

Greece in this period is not yet the Greece of Olympic games, marble temples, and lifelike sculptures that was to emerge in later centuries. This may, however, be the period to which the Homeric epics refer (although it is not likely the period in which they were crafted); certainly the ancient Greeks thought that the events of these epics took place in this time period. When we speak of Greek culture at this time, we are speaking of a collection of numerous independent city-states, scattered throughout mainland Greece and the islands of the Mediterranean and the Aegean Sea and populated by a people who spoke an archaic form of Greek, which they wrote in a script known today as Linear B. These early Greeks are referred to as Mycenaeans because the obviously once-powerful and rich city of Mycenae in the Peloponnese was the first site of this culture excavated on the Greek mainland. Moreover, the *Iliad* records that the prince of Mycenae was the head of the Achaean (the self-referential name used by these early Greeks) confederation that attacked Troy but only as a first among equals. Mycenaean architecture and pottery is distinctive, and archaeologists have tracked Mycenaean artifacts and other forms of material culture throughout the eastern Mediterranean, clear evidence of a wide trade web and a long cultural reach.

Most scholars assume that the Homeric epics refer to this Mycenaean culture. Written down well after 1000 BCE, the *Iliad* and the *Odyssey* may partially reflect the values and social institutions of this earlier period, deemed by Greeks in centuries that followed as “heroic.” It is fitting, then, that the archaeologist who first identified the Mycenaeans, Heinrich Schliemann, is also credited with having discovered the lost city of Troy, the setting for the *Iliad* and the Trojan War. His

archaeological work at Troy was deficient by modern standards, but the site in Turkey remains a fantastic tourist destination and a monument to these Homeric heroes. What exactly happened to Mycenaean civilization is unclear. Destruction layers throughout the region suggest that it was wracked by war, and Greek tradition records that following the Trojan War, Greek cities became embroiled in internecine wars. The concomitant appearance of Greeks within the group known in ancient texts as the Sea Peoples (who attacked Anatolia, Egypt, and Syria-Palestine) suggests that much of Mycenaean civilization was displaced. Some Mycenaean sites, such as Mycenae, were deserted, whereas others, such as Athens, remained inhabited. The appearance of significant amounts of Mycenaean pottery at sites on the coastal Levant suggests that the Mycenaeans were the ancestors of the Philistines (of biblical infamy).

Farther west were the cultures of southern Italy, Iberia, Portugal, and the islands of Corsica, Sardinia, Sicily, and Malta, all of which displayed a wide range of lifestyle traditions, from small permanent villages to temporary camps. Iberia's traditions of tomb construction and copper metallurgy are noteworthy, and significant contact with North Africa is evident in the preponderance of African materials found in the tombs (for example, ostrich eggs). Rock-cut tombs in southern Italy and Sicily contained drinking vessels and weapons and showed similarities to cultures in the Alpine regions of Italy. From around 3600 to about 2500 BCE, megalithic temples were important components of life on Malta. These temples are some of the oldest (still-existing) freestanding structures in the world, and although each was built to a unique plan, their shared construction practices and architectural features point to a great deal of continuity over their 1,000 years of use. Ports around the Mediterranean Sea acted as nodal points in a vast network and were major points of contact among European, African, and Near Eastern cultures.

South Asia

When scholars discuss the emergence of the first known complex civilizations, the three regions cited are Egypt, Mesopotamia, and India. Since scholars cannot read the earliest Indian scripts (if these can even be considered scripts), we know far less about early Indian civilizations

than about these other regions. Most of what we know about early India comes from archaeology and from later accounts of the region.

Specialists call the first complex civilization in India either the Indus Valley People or the Harappans. The Indus Valley in present-day Pakistan was the location of the first large cities in the Indian subcontinent, perhaps as early as 3200 BCE. Certainly by 2500 BCE, the Indus Valley was

the location of major urban centers. Harappa is the name of one of the two largest cities excavated to date (Mohenjo-daro is the other). Indus

Specialists call the first complex civilization in India either the Indus Valley People or the Harappans. The Indus Valley in present-day Pakistan was the location of the first large cities in the Indian subcontinent, perhaps as early as 3200 BCE.

Valley culture was not uniform; while there are numerous similarities among the ancient cities, there are also significant local variations. Generally, though, the cities follow an organized civic plan, with identifiable subdivisions and possibly professional quarters. Monumental buildings are present in most town plans. The functions of these buildings are not clear; they could have functioned as governmental offices, religious centers, storage areas, or public meeting places.

The Indus Valley civilization had trade contacts with regions as distant as Europe. It is not likely that Europeans met face-to-face with Indus Valley people during this period. Rather, this contact was what archaeologists refer to as “down-the-line-trade” in which goods travel through successive territories through a series of intermediaries. Thus, the person at the beginning of the chain and the person at the end have little knowledge of one another. There is good evidence, however, for direct trade with the people of ancient Iran, and it is likely that the Mesopotamians traded (to some extent) with the Indus Valley as well. Distinctively Mesopotamian objects, such as cylinder and stamp seals, are found at Indus Valley sites, and locations mentioned in cuneiform texts likely refer to places in South Asia.

The urban basis of Harappan civilization began to erode around 1900 BCE, and by 1750 BCE Mohenjo-daro had been abandoned. However, the disappearance of Harappan culture was not quick, and some scholars have argued that Indus Valley material culture persisted as late as 1000 BCE. Life in India changed dramatically in the centuries that followed the decline of Harappan civilization. The population center shifted from the Indus River to the Ganges River, but what exactly caused this is debated by historians. The traditional understanding of this period is that a group of people (referred to as Indo-Aryans) invaded the region and brought new technologies (the chariot) and new traditions (preserved in the Vedas). For this period we have some textual evidence, textual evidence that shows that these people spoke an Indo-European language or Indo-Aryan language (the terms are used interchangeably). Scholars debate whether this actually reflects a migration of a new population into India at this time or whether the people of ancient India had been using an Indo-European language for quite a while. The theory of an Aryan migration has come into question (and is discussed at length in the encyclopedia). Since we cannot read any of the Harappan scripts, we do not know if this was an Indo-European language or something entirely different. Whatever their origins, the inhabitants of the Gangetic Plain were the authors of the Vedas, the oldest religious texts still used by faith communities today. The Vedic texts are the oldest sacred texts in Hinduism, and while most of their written composition (as opposed to oral transmission) dates to after 1000 BCE, many of their values and traditions reflect life in India during this time.

Central Asia

The argument that Indo-Aryan groups moved into India at the end of the Harappan civilization is based on evident similarities between these people and groups living in central Asia at this time. These people dwelt

throughout the Eurasian steppe, and a number of different cultures have been identified by archaeologists based on their material remains and later linguistic evidence. These cultures were very diverse, but in general these people resided in small fortified villages or mobile camps. Pastoralism was a fundamental component of their subsistence practices, although some of these groups (for example, the Bactrian-Margian Cultural Tradition) were farmers. The horse was domesticated at some point in this period (or slightly earlier), and after this it became a fundamental component of Eurasian life, especially on the steppes of central Asia. Some scholars argue that the horse was first domesticated around 3500 BCE in this region by the Botai culture of present-day northern

Some scholars argue that the horse was first domesticated around 3500 BCE in this region by the Botai culture of present-day northern Kazakhstan. However, it is possible that these people simply hunted wild horses. The issue remains debated.

Kazakhstan. However, it is possible that these people simply hunted wild horses. The issue remains debated. Much of what we know of the people of central Asia in this period comes from archaeological excavations of their burials. For example, archaeologists working at Gonur-Depe in Turkmenistan have recently uncovered a cemetery dating to about 3000 BCE filled with numerous types of grave goods, including vases, jewelry, and silver artifacts.

Prefiguring the Silk Roads that emerged in later centuries, central Asia prior to 1000 BCE was one of the key locations connecting China and East Asia with West Asia, South Asia, Europe, and the Near East. Mummies found in the Tarim Basin (the location of the Taklamakan Desert) dating to around 1800 BCE may have genetic links to the people of western Eurasia. After this period, the people in the Tarim Basin are known to have spoken a language called Tocharian, which is an Indo-European language (and the Indo-European language spoken farthest east; most were spoken in regions that later became known as Europe). It is likely that the mummies of the Tarim Basin were the Tocharians' predecessors and, if so, points to substantial contact between western and eastern Eurasia.

Other evidence shows how central Asia linked Asia, Europe, and the Near East. The war chariot is a technology that may have been invented in western central Asia (although this is debated by scholars) and was transmitted to China through this region. Chariots buried in graves (presumably along with their ancient drivers) have been found as early as 2000 BCE in sites associated with the so-called Timber-Grave culture, located along the Tobol River in Russia. Various grains that were first cultivated in the Near East (such as wheat and barley) were likely brought to China through central Asia. These Near Eastern cereal crops went on to have a profound effect on northern Chinese cuisine. The mineral resources of Afghanistan were much desired by the people of the ancient Near East; most certainly the lapis lazuli that is associated with some of the finest Egyptian art was imported from central Asia. Similarly, the mineral resources of the Taklamakan desert were desired in China, and perhaps as early as this period nephrite jade was imported from here after local Chinese sources in the Yangzi River region were depleted.

China and East Asia

By the beginning of this period, rice cultivation was well established in southern China, whereas cereal crops such as millet (introduced from West Asia) were raised in the loess soils of the Yellow River. During 4000–3000 BCE, China is characterized by diverse agricultural communities. It is not entirely clear to archaeologists how these different groups were related to one another if at all. Generally, scholars refer to them according to the geographic region in which they are found or the first site at which they are identified. Different villages are grouped together by archaeologists based on location as well as shared material culture.

At some point in the period from 4000 to 1000 BCE, these small villages formed into larger political units. Exactly when and how these early Chinese states formed remains considerably difficult for scholars to reconstruct. Chinese traditions suggest that the first Chinese states arose around 2100 BCE in what is referred to as the Period of the Three Dynasties. The first of these was the Xia dynasty, which until recently most scholars took as entirely mythical. Following the Xia, according to the traditional accounts, was the Shang dynasty (traditionally dated from 1544 to 1045). The Shang state is well attested both archaeologically and historically in northeastern China and the Yellow River valley. It eventually gave way to the Western Zhou dynasty, according to tradition in 1045 BCE, a dynasty that is said to have lasted until 771 BCE.

Current scholarly opinion regarding the accuracy of the traditional accounts of Chinese history has changed dramatically in response to archaeological exploration. Until recently, scholars considered the Shang to be the first truly historical dynasty and the first period in which a Chinese state can be said to have emerged. The first of these was the Xia dynasty. Recent archaeological excavations suggest that the situation was somewhat more complex. Rather than affirming that there was no Xia dynasty, many scholars now believe that the archaeological evidence proves that there was such a dynasty but that our chronological understanding of this period has been mistaken. The Period of the Three Dynasties, rather than consisting of three successive dynasties, is better understood as consisting of three concurrent dynasties with different and successive periods of hegemony. If this was the case, then the latter half of this period in China is much more complex than previously thought. What seems most probable is that from about 2100 BCE on, the small villages in China became increasingly unified into small chiefdoms. These chiefdoms (one of which may have been the basis for the Xia of later myth) competed with one another for power and authority. Around 1500 BCE one of these chiefdoms, the Shang, emerged as the most powerful, later to be supplanted by the Western Zhou.

The situation in Japan at this time is not quite as confusing for historians as that of China, but it does have its uncertainties. Around 5000 BCE, Jomon culture (named after its distinctive pottery styles) had spread throughout the Japanese archipelago, and by roughly 4000 BCE there was a dramatic increase in population density, but most Jomon sites were still small villages. At this time, the Jomon people subsisted on marine life (especially clams) and wild game. Around 3500 BCE, the

Recent archaeological discoveries, however, suggest that our understanding of ancient Japan may overemphasize the Jomon culture and that there may be a greater variety of cultural differentiation than was previously thought.

Jomon began practicing agriculture. Yams and taro roots were probably introduced via China (perhaps originally from the Malay Peninsula), and a variety of agricultural practices were developed. Rice agriculture did not arrive until later. Recent archaeological discoveries, however, suggest that our understanding of ancient Japan may overemphasize the Jomon culture and that there may be a greater variety of cultural differentiation than was previously thought.

The rest of the Pacific Rim is not so well understood by archaeologists. Other parts of Southeast Asia (such as the areas now encompassed by Vietnam and Thailand) were inhabited, interacting with China and developing rice agricultural and metalsmithing techniques. Traders traveled from Asia to Australia (possibly bringing with them dingoes). These traders are attested archaeologically through their distinct stone tools, and their material culture is referred to as the Stone Tool Tradition, although the usefulness of this term for understanding the period is currently debated. The first migrations to Polynesia occurred in this period, made possible by the invention of the double-hulled canoe that allowed long journeys across the ocean. By 1600 BCE, people known by the term “Lapita” began colonizing the islands of the South Pacific.

Ultramontane Europe

The beginning of this period in Europe is marked by the florescence of agriculture as the dominant mode of subsistence and the appearance of regional diversity. These cultural traits started to appear around 4500 BCE and become normative for most of Europe by about 4000 BCE. Although material culture and social practices varied throughout Europe, for most Europeans at this time the small village was home. These small villages were linked through informal trade networks, and evidence of warfare suggests that relations were not always friendly. These inter-village connections waxed and waned throughout the Bronze Age. Some types of material culture spread throughout most of Europe, pointing to shared values and aesthetic sensibilities. Likewise, burial practices became steadily more uniform, suggesting common beliefs about the after-life (or at least common beliefs about how the dead should be treated). The cultures of this time period are referred to by a bewildering variety of names, often based on a distinctive type of material culture (the Corded Ware and Beaker people are both named after distinctive pottery) or cultural practices (the Urnfield people are named after their burial customs).

While most of the material culture from this period in Europe is meager, there are some noteworthy exceptions. Metallurgy, especially in the Carpathian Basin and Scandinavian regions, reached a high level of technical and artistic skill. Rock art is found in mountainous regions,

such as the Alps or Pyrenees, and was probably much more widespread. The evidence for rock art elsewhere may have been destroyed over the past few thousand years. Monumental architecture is rare and mostly involves standing large stones (called megaliths) in patterns on the landscape. The most noteworthy of these monuments is Stonehenge, which still has the power to awe. However, this was not the only “henge” monument or megalithic structure in Western Europe. Over 1,000 of these monuments have been found throughout the British Isles, Ireland, and France (dating roughly from 3500 to 1200 BCE); thus, they reflect a larger regional culture that saw meaning in these kinds of constructions.

The Americas

Our evidence for life in the Americas from 4000 to 1000 BCE is significantly less than in other regions. Much of this has to do with issues of archaeological preservation. Scholars assume that this is a period of growing regional diversity, but the material manifestations of this (houses, clothing, language) have not, for the most part, survived. Scholars tend to emphasize the study of later periods in the Americas, where evidence is present on a grander scale. However, it is a mistake to ignore this period, as many fundamental changes in American civilizations occurred.

North America

With a few major exceptions, culture in North America from 4000 to 1000 BCE is particularly ill-attested. It is certain, however, that this was a time of growing cultural complexity in North America. The environment changed dramatically in this period, with the appearance of the distinct environmental regions that are currently present in North America. Over the course of these three millennia, people living in these different regions developed cultural practices that made sense for their particular environment. It is impossible to speak generally of a unified North American culture by 1000 BCE because there is so much variety in the material record.

One of the major changes to the North American lifestyle was the development of new approaches to food acquisition. In an earlier era, the big game species that many North American peoples had relied on as the major part of their subsistence practices disappeared. The big game had been widespread and were best exploited through mobile hunting strategies. With their disappearance, early North Americans adopted different approaches to food procurement. Some, such as the people of the Plains, maintained mobile hunting practices. Bison became a fundamental resource, and new methods of hunting these animals developed, as is in evidence at the site of Head-Smashed-In Buffalo Jump in Alberta, Canada. The Koster site, in the Illinois River valley of the Eastern Woodlands, shows evidence of a different process, a trend toward permanent year-round settlements. In general, archaeologists are

now recognizing that social complexity increased dramatically in the Eastern Woodlands in the period from 4000 to 1000 BCE, concomitant with a dramatic increase in population.

The American Southwest also shows increasing social complexity during this period. There are interesting similarities and continuities, dissimilarities and discontinuities, with the cultures of Mesoamerica. On the one hand, during this period the people of the American Southwest adopted farming practices that were clearly learned from their Mesoamerican neighbors. On the other hand, these people did not adopt the intense social stratification, writing, or monumental architecture of the Mesoamericans with whom they had contact. Clearly, also, the people of the Southwest participated in long-distance exchange networks and acted as a major link between Mesoamerica and the Great Basin and Plains of North America.

Mesoamerica

The period from 4000 to 1000 BCE straddles two major chronological divisions, as seen by Mesoamerican archaeologists. The first half continues the Archaic period from earlier centuries; the Archaic period is characterized by the transition from a reliance on wild animals and plants to a domesticated agricultural lifestyle. The people of Mesoamerica started living in villages, basing their economy on small-scale agriculture. Maize, while domesticated at or before the beginnings of this period, became the staple of the Mesoamerican diet and the crop that allowed complex civilization to develop in this region. Perhaps around 1500 BCE, the use of maize as a major crop spread out of the Mexican highlands into parts of North America, South America, and maybe even the Caribbean.

The rise of complex civilization was characteristic of the Formative period, the second major chronological division within this period.

Were these early Olmec people a type of mother culture from which all complex civilizations in this region emerged, or were there numerous complex cultures at this time that eventually came to be dominated by the Olmecs?

Cities became the centers of political and religious authority concomitant with a dramatic increase in the stratification of wealth and power. Pottery appears in this period, as does monumental architecture. In this period, the foundations of Mesoamerican life (until the Spanish conquest) were established. Scholars, however, are quite divided on how these early cultures developed and how they relate to the later cultures of the region. Toward the end of

this period, the Olmec people had emerged. Were these early Olmec people a type of mother culture from which all complex civilizations in this region emerged, or were there numerous complex cultures at this time that eventually came to be dominated by the Olmecs? This is the most difficult controversy in Mesoamerican archaeology of this time period.

South America

Complex civilization also arose in South America. By about 3000 BCE, small villages were established in the Andes and coastal Peru. By around 1000 BCE, many of these small villages had become larger centers. However, this process was not uniform. For example, the city of Caral in the Supe Valley grew into a major center during 3100–2600 BCE. People living on the coast ate a combination of fish, shellfish, and cultivated crops and also built large stone mounds (such as at the site of Aspero, in present-day Peru). From 2500 to 2000 BCE, sites in the north-central highlands of Peru appeared that seem to have been focused on ceremonial activity. One of these sites, Kotosh, gives its name to a religious system that lasted for the next 1,500 years in which people would meet in small buildings with built-in fire pits and benches around the walls, similar to kivas found in the southwestern United States. Starting around 2200 BCE (and lasting until 1100 BCE), people began moving inland from the coast to take advantage of new developments in irrigation agriculture. Irrigation agriculture may have allowed populations to grow substantially. With these larger populations came woven textiles, pottery, and monumental architecture. This monumental architecture typically consisted of U-shaped platform mounds made of stone and is found at sites such as Sechin Alto. The northern and southern Andes are less well understood for this period. It should be noted that some of the earliest pottery in the Americas was manufactured by the Valdivia culture (3500–1500 BCE) in northern Colombia. The Valdivia culture changed considerably over this 2,000-year period, with sites becoming larger and displaying signs of increasing social complexity throughout this stretch of time. The Chinchorro culture, which originated in the centuries that preceded this period, survived in the southern Andes until about 2000 BCE and continued to develop mummification practices that involved the flaying of the deceased and the reconstruction of the body with materials such as straw, reeds, and clay. The first monumental architecture in the southern Andes appears around 1300 BCE near Lake Titicaca. The best example of this is found at the site of Chiripa, which features a large sunken courtyard surrounded by a number of buildings.

Outside of the Andes, other parts of South America saw moves toward sedentarization and urbanization. People living in the Amazon seem to have been connected to those living in the eastern Andes through a network that is evidenced through shared material culture. The movement of pottery forms can be traced all along the Upper Amazon and into Peru, and around 2000 BCE this is especially in evidence.

In summary, the period from 4000 to 1000 BCE was a period of innovations, many of which we take for granted today. These included writing, state-level governance, and law, but they also included the development of class differences, state-level warfare, and gender inequalities institutionalized within legal and political frameworks. This was the birth of civilization, for good and for ill.

Environment and Population

The people of the Late Bronze Age town of Akrotiri in Greece must have known that their entire city was about to be destroyed. When Spyridon Marinatos began excavations of the town in 1967, he did not find many bodies. The ancient villagers had abandoned their sophisticated town just before the volcanic eruption of Thera. Nearly 3,500 years ago, this eruption covered the city with a heavy layer of volcanic ash. The ash, over 26 feet (8 meters) high in some places, had preserved the ancient Minoan town as it had been in the Bronze Age, including remnants of its indoor plumbing and walls covered in beautiful painted frescoes.

Archaeologists thrive on natural disasters (such as the eruption of Thera). Most archaeological work involves sifting through the garbage left behind by ancient people. Major calamities, however, prevent people from making changes to their lifestyle or removing valuable objects, and as a side effect, they leave behind valuable information for archaeologists. Unexpected changes in climate can be devastating for the human populations who eke out a fragile existence based on environmental regularity and predictability. A natural disaster can upset this balance. In the case of the eruption of Thera, there was little that humans could do to prevent or withstand the devastation. Successful societies were able to develop means of surviving and thriving in their environment. Barring unforeseen changes, such as volcanic eruptions, human settlements in the period from 4000 to 1000 BCE developed in response to the growing ability of humans to manage their environment. In this period, human societies emerged in a variety of different environmental locations throughout the world, such as the arid deserts of Egypt, the temperate forests of Europe, and the tropical rain forests of the Amazon.

By 4000 BCE, a much higher proportion of the world's population had become farmers and herders. Agriculture and the utilization of domesticated crops grew in importance from 4000 to 1000 BCE and by the end of that period, people in the Near East, parts of Africa, Europe, South Asia, parts of central and East Asia, and parts of the Americas relied on farming to support the ever-increasing population. With agriculture playing a more important role in subsistence practices, new crops and food products derived from cultivation became prominent. Beer and wine, although probably invented earlier, became important drinks in Egypt, the Near East, and the Mediterranean. Oils (such as olive oil, palm oil, and sesame oil) were used as food and fuel and were an important means of storing agricultural products and preventing them from spoiling. Rice spreads farther throughout East Asia, and other crop types spread throughout Africa. Maize farming moves out of Mesoamerica into what is now the southern United States and into South America.

With larger populations came larger settlements, and an increasing trend toward urbanization is noteworthy throughout much of the world in this period. Although the majority of people did not live in what could be called cities, urban areas became the centers of power and authority in many regions. New approaches to disposing of domestic waste and garbage are innovations that have had a profound impact on human lifeways. The beginnings of concerns regarding sanitation are often ignored by historians and yet were fundamental to successful urban life.

As distinctions between urban and rural became apparent, so did distinctions between sedentary groups and nomadic and seminomadic groups, although often these groups relied on one another for different resources. Often these seminomadic groups were pastoralists who were compelled to move in order to allow their herds to graze. Sometimes these pastoralists were seen as part of the larger community (although marginal members), as was the case in Egypt and Mesopotamia. In other instances, pastoralists were seen as a completely separate community, as was the case with the Andronovo culture who lived in the steppes of central Asia and traded with the settled Bactrian-Margian culture.

Environmental change was a fact of life for the people of this period, regardless of whether they lived in urban centers or in temporary campsites. The Sahara began warming up during this period, pushing people out of North Africa, a process that continued in the centuries that followed. Volcanic eruptions may have also had a negative impact on farming, although how wide the impact of these eruptions was on

the environment is debated by scholars. The changing courses of the Tigris and Euphrates rivers are apparent, and the people of Mesopotamia altered their landscape tremendously by building canals off of these rivers for irrigation. The extinction of big game throughout North America prior to this period had led the people of that region to adapt a variety of diver-

The changing courses of the Tigris and Euphrates rivers are apparent, and the people of Mesopotamia altered their landscape tremendously by building canals off of these rivers for irrigation.

gent subsistence techniques suited to their local environment, as opposed to practices that could be utilized throughout the continent. Another approach to managing the environment at this time was the use of religious or magical practices to control climatic events. Although historians do not presume that these practices were efficacious, the environment was extremely important in many of the religious traditions of the period from 4000 to 1000 BCE.

Modern archaeologists are subject to the whims of the environment in which they work, just as these ancient civilizations were. The climate is not much of a problem for actually doing the archaeological work (although excavating in Egypt in June can be far from comfortable!); rather, it is a problem for what archaeologists can actually find. Environmental conditions are the most important factor in archaeological preservation. The climate, soil type, humidity level, and changing geomorphology of the earth profoundly affect what types of artifacts survive in the archaeological record. An archaeologist must understand

the environmental conditions of the site, since these conditions directly affect what will be found. Generally, inorganic materials (such as stone tools and clay) can withstand a diversity of environmental conditions. Metals, however, are a different matter. In very acidic soil, metal (especially copper and bronze, the two metals most frequently used in this period) oxidizes, eventually deteriorating into a green- or rust-colored stain. Organic materials, anything derived from animals or plants, do not fare as well archaeologically. Decomposition processes vary dramatically depending on the nature of the matrix (the material, usually soil, that surrounds the object). Bone is preserved well in chalky soils but is completely destroyed by acidic soils.

The best types of preservation conditions are the most extreme conditions: wet, dry, and frozen regions yield the best-preserved artifacts. Wet or waterlogged areas that have not been disturbed (such as peat bogs or shipwrecks) seal remains away from air, thus preventing the development of decomposing agents. Once an artifact is removed from a waterlogged site, however, it begins to deteriorate very quickly, so archaeologists must employ conservation techniques immediately. Dry regions desiccate organic materials and typically destructive microorganisms cannot survive in these types of environments. Thus, bodies buried in the Egyptian desert are already well located for mummification. Frozen environments, such as that which trapped poor Oetzi, work as natural refrigerators.

When we are exploring the cultures of this period, it is thus important to keep in mind how the environment affected what archaeologists were able to recover. The best organic materials come from Egypt because of the dry climate. The most texts come from Mesopotamia, since the Mesopotamians wrote on nearly indestructible (inorganic) clay tablets. The preservation in Neolithic sites in China varies dramatically across the country, given the diversity of environmental conditions. The varying treatment of world cultures does not reflect a varying level of importance to world history. Rather, it reflects a varying level of environmental suitability for the preservation of evidence.

Introduction: Ancient Chronology

One of the most challenging issues facing scholars of ancient world history is how to integrate chronological systems from different regions. The chronological understanding of this period is imperfect, in part due to difficult textual sources and in part due to some of the vagaries of scientific dating techniques. In regions where we have written accounts from the period, scholars can utilize these ancient dates, but this is much more difficult than it may seem at first since the ancients had different means of reckoning time than moderns have. Converting ancient dates into modern dates involves introducing some margin of error. Since the late 1940s CE, archaeologists have been able to use scientific dating techniques, such as radiocarbon dating, that can provide “absolute dates.” Dates that are derived from these techniques are generally

accurate but themselves all have some margin of error and thus leave some ambiguity. Archaeologists often use relative dating techniques, techniques that involve understanding when events happened in relation to other dates. Relative dating techniques often involve the study of material culture changes over time and are often based on the analysis of changes of material culture over time. In general, when working with dates in this period, remember that these are often just working dates and may be inaccurate.

Egyptian Chronology

Predynastic Period	5300 BCE	3000 BCE
Dynasty 0	3200 BCE	3000 BCE
Dynasty 1	3000 BCE	2890 BCE
Early Dynastic Period	3000 BCE	2686 BCE
Dynasty 2	2890 BCE	2686 BCE
Dynasty 3	2686 BCE	2613 BCE
Old Kingdom	2686 BCE	2160 BCE
Dynasty 4	2613 BCE	2494 BCE
Dynasty 5	2494 BCE	2345 BCE
Dynasty 6	2345 BCE	2181 BCE
First Intermediate Period	2181 BCE	2055 BCE
Dynasty 7	2181 BCE	2160 BCE
Dynasty 8	2181 BCE	2160 BCE
Dynasty 9	2160 BCE	2025 BCE
Dynasty 10	2160 BCE	2025 BCE
Dynasty 11	2125 BCE	1985 BCE
Middle Kingdom	2055 BCE	1650 BCE
Dynasty 12	1985 BCE	1773 BCE
Dynasty 13	1773 BCE	1650 BCE
Dynasty 14	1773 BCE	1650 BCE
Dynasty 15	1650 BCE	1580 BCE
Dynasty 16	1650 BCE	1550 BCE
Second Intermediate Period	1650 BCE	1550 BCE
Dynasty 17	1580 BCE	1550 BCE
New Kingdom	1550 BCE	1069 BCE
Dynasty 18	1550 BCE	1295 BCE
Dynasty 19	1295 BCE	1186 BCE
Dynasty 20	1186 BCE	1069 BCE
Third Intermediate Period	1069 BCE	664 BCE
Dynasty 21	1069 BCE	945 BCE

Egyptian Chronology

From 3000 BCE and well through 1000 BCE, these two regions (Upper and Lower Egypt) remained culturally unified (if not always politically unified). The chronological system that scholars use to describe Egypt reflects this. The Old Kingdom, the Middle Kingdom, and the New Kingdom refer to periods in which Egypt was unified under a central government. Following each of these periods is an Intermediate period (the First, Second, and Third, respectively); the term “Intermediate” is used to acknowledge that there was a breakdown in centralized authority in that time. At those times there was often more than one dynasty operating at the same time, controlling different parts of the country. Thus, the dates for some of these dynasties overlap. The designation “Predynastic” is used to refer to the period of Egyptian history that dates to before the advent of the unified state. Dynasty 0 is a somewhat confusing term; it is used by scholars to refer to the earliest dynasty that ruled over a unified Egypt, a dynasty that was unknown when scholars began numbering the dynasties. The dates for the Old Kingdom and the Middle Kingdom have a margin of error of up to about 50 years (and as much as 150 years for the Early Dynastic period). The dates for the New Kingdom have a margin of error of about a decade. These dates are based on ancient observations of astronomical phenomena, but the location from which the phenomena were observed is unknown and is the source of the ambiguity. Note that all of the dates presented here are disputed, but these are the most commonly accepted by Egyptologists today.

Mesopotamian Chronology

Perhaps one of the most difficult issues for students when they start studying Mesopotamia is getting a handle on chronology. Unlike Egypt, which existed as a unified state for much of this period, Mesopotamia did not, and thus there has never developed a consistent terminology for referring to its own past. Modern scholars have had to create this terminology as they have recovered the lost Mesopotamian traditions. This means that the periods do not always match up well together and are not always meaningful for all of the people between the two rivers. The chronological system used at the beginning of this period (4000 BCE) is entirely based on material culture. Around 2350 BCE, scholars designate periods according to the ruling dynasties. This initial change in designation is problematic because the Mesopotamians did not immediately change their material culture (houses, pottery, etc.) because a new ruling dynasty took over, so some overlap is expected. Likewise, since there was not always a smooth succession from one dynasty to another, designations based on dynasty often overlap or do not fully capture the actual diversity of the ancient political system.

In terms of absolute dates, Mesopotamian chronology is on relatively certain ground. The ancient Mesopotamians were expert astronomers and recorded various astronomical phenomena. Since modern astronomers can calculate when events such as eclipses occurred, it is possible to “translate” ancient Mesopotamian dates into our calendar. There are still some ambiguities. Since the Mesopotamians thought that eclipses were bad omens, it is possible that later historians in Mesopotamia assumed that eclipses occurred around certain calamitous events. While the details of the chronological problems are too complex to get into here, you should be aware that the exact dates surrounding King Hammurabi’s reign are disputed, and thus many of the dates that are calculated based on Hammurabi’s traditional dates are also in question.

Mesopotamian Chronology

Uruk Period	4000 BCE	3200 BCE
Jemdet Nasr Period	3200 BCE	2900 BCE
Early Dynastic Period I	2900 BCE	2700 BCE
Early Dynastic Period II	2700 BCE	2600 BCE
Early Dynastic Period III	2600 BCE	2350 BCE

Syro-Palestinian Chronology

Be wary of historians who refer to the Levantine chronology in the period from 4000 BCE to 1000 BCE using biblical terminology (i.e., the Patriarchal period, the period of the Judges). Mainstream scholars are quite divided on which (if any) of these biblical periods reflect a historical reality, and there is certainly little agreement on when these periods and events should actually be dated. Most scholars of Syria-Palestine use archaeological terminology when discussing chronology in this region in order to avoid these problems altogether. This era begins in the middle of the Chalcolithic period, otherwise known as the Copper

Syro-Palestinian Chronology

Chalcolithic Period	4300 BCE	3300 BCE
Early Bronze Age I	3300 BCE	3050 BCE
Early Bronze Age II/III	3050 BCE	2300 BCE
Early Bronze Age IV/Middle Bronze Age I	2300 BCE	2000 BCE
Middle Bronze Age IIA	2000 BCE	1800 BCE
Middle Bronze Age IIB/C	1800 BCE	1550 BCE
Late Bronze Age	1550 BCE	1200 BCE
Iron Age I	1200 BCE	1000 BCE

Age. Most of the period from 4000 BCE to 1000 BCE is considered the Bronze Age, which is subdivided into Early, Middle, and Late (and then each of these periods is further subdivided first by Roman numeral and then by a letter). The last stages of this period in Syria-Palestine are in the Iron Age (specifically the Iron I). Scholars are not entirely in agreement about what constitutes the beginning of one period and the end of another, so you will often find different dates or nomenclature in use. Our understanding of the time periods also changes with each new archaeological discovery, but it becomes too confusing to change the name of each period. So, confusingly enough, bronze is still used in the Iron Age, and iron is first invented in the Bronze Age! In other cases, scholars will generally agree on what constitutes a time period but will not agree on what to call it. For example, most scholars are in agreement that the Early Bronze IV period and the Middle Bronze I period are the same. But no one agrees on which term should be used. Presented here is a conservative chronological scheme that is commonly used.

Greek Chronology

Early Cycladic Period	3000 BCE	2000 BCE
Early Helladic Period	3000 BCE	2000 BCE
Early Minoan Period	3000 BCE	2000 BCE
Middle Cycladic Period	2000 BCE	1600 BCE
Middle Helladic Period	2000 BCE	1600 BCE
Middle Minoan Period	2000 BCE	1600 BCE
Late Cycladic Period	1600 BCE	1500 BCE
Late Helladic I Period	1600 BCE	1500 BCE
Late Minoan Period	1600 BCE	1050 BCE
Late Helladic II Period	1500 BCE	1450 BCE
Late Helladic IIB Period	1450 BCE	1400 BCE
Late Helladic IIIA Period	1400 BCE	1300 BCE
Late Helladic IIIB Period	1300 BCE	1200 BCE
Late Helladic IIIC Period	1200 BCE	1050 BCE

Chronology of Greece and the Greek Islands

The chronology of Greece and the Greek islands in this period is based on archaeological excavations and understandings of the change of material culture over time. The dating systems are divided into three geographic regions: Helladic, Cycladic, and Minoan. Helladic dates refer to mainland Greece. Cycladic dates refer to the Cyclades, an island group in the Aegean Sea. Minoan dates are based on archaeological excavations on the island of Crete. None of these dates are precise, but those that are presented here are commonly used by archaeologists.

Indus Valley Chronology

The chronology of the Indus Valley civilization is based entirely on archaeological evidence. The beginning of this period, in 4000 BCE, is also the beginning of the Pre-Harappan or Early Harappan phase, which lasts until about 2600 BCE. The Mature Harappan phase (the period in which the Indus Valley civilization seems to peak) starts in 2600 BCE and lasts until about 1900 BCE. Scholars are uncertain about exactly how Harappan civilization comes to an end. By 1750 BCE, substantial urban occupation of the cities of Harappa and Mohenjo-daro had come to an end, but recent excavations have shown that this may not have been the case elsewhere. The origins of the Vedic Age are particularly contested since scholars debate the relationship between the culture of this period and the preceding Indus Valley civilization. The term “Vedic” refers to the Vedas, sacred texts that were composed during this period.

South Asian Chronology

Early Harappan	3300 BCE	2600 BCE
Mature Harappan	2600 BCE	1900 BCE
Late (Post-urban) Harappa	1900 BCE	1300 BCE
Beginnings of the Vedic Age	1300 BCE	ca. 500 BCE

East Asian Chronology

Chinese chronology for the period from 4000 BCE to 1000 BCE is under constant revision, as archaeological excavations demonstrate an increasingly complex situation. The general picture that has emerged regarding

Early Jomon	7500 BCE	3000 BCE
Middle Jomon	3000 BCE	2000 BCE
Late Jomon	2000 BCE	1000 BCE

China at the beginnings of this period is that there were a variety of independent Neolithic cultures within the region. The dates for these individual cultures are presented here, most of which are based on radiocarbon dating and have a high margin of error. The dates of Chinese dynasties given reflect scholarly adaptations of traditional dates and also involve more standard of error than may appear here. Japanese dates are presented for the Jomon culture, and all of these are derived from archaeological excavations.

European Chronology

European Chronology		
Mesolithic Period	12000 BCE	3000 BCE
Neolithic Period	7000 BCE	3500 BCE
Copper Age	4500 BCE	2300 BCE
Bronze Age	2300 BCE	800 BCE

The chronology of Europe and western Asia in this period is extremely complex. Since the cultures of Europe in this time are very diverse, their material culture is very diverse, so it is difficult to identify overarching trends that accurately reflect European society. To deal with this, European archaeologists who work in this period generally use two types of chronologies. The first type is a local chronological

system that makes sense only for a small region. The second type, originally referred to as the Three-Age System (and the basis for the system used in Syria-Palestine) references metallurgical technology: Stone Age, Copper Age, Bronze Age, and Iron Age. These terms are used very broadly, and even though technological capabilities varied dramatically in Europe, archaeologists use these designations to talk about Europe as a whole. Note that these dates in Europe are not the same as the dates in Syria-Palestine; the two systems have developed independently and need to be “translated.”

Chronology of the Americas

North American Chronology		
Middle Archaic (Eastern Woodlands)	6000 BCE	3000 BCE
Archaic (Southwest)	6000 BCE	200 CE
Archaic (Plains)	5000 BCE	1 CE
Late Archaic (Eastern Woodlands)	3000 BCE	1000 BCE

Mesoamerican Chronology		
Middle Archaic Period	5500 BCE	3500 BCE
Late Archaic	3500 BCE	2000 BCE
Initial Formative Period	2000 BCE	1200 BCE
Early Formative Period	1200 BCE	900 BCE

South American Chronology		
Archaic (Preceramic)	8000 BCE	2000 BCE
Early Formative Period	3500 BCE	1500 BCE

Scholars use the broad term “Archaic” to refer to the Americas through much of the period from 4000 BCE to 1000 BCE. This is the second stage of human occupation in the region in the schema developed by Gordon Willey and Philip Phillips and is characterized by subsistence practices that are utilized before farming is introduced. The introduction of farming marks the end of the Archaic in many regions and the beginning of the Formative period. Various subdivisions are used in different regions, acknowledging that there was actually a significant diversity of cultures in the Americas throughout this period, despite this broad chronological framework.

—Kevin M. McGeough

■ Introduction: The Environmental Framework

From 4000 BCE to 1000 BCE, people gained a greater degree of control over their environment, continually developing the skills, knowledge, and technology that allowed them to survive and thrive in a variety of environmental conditions. These ancient humans were able to see the potentials and possibilities in their local regions and adapt themselves and their surroundings accordingly. They were capable of long-term environmental planning and management, although ancient environmental management did not involve conservation or sustainability,

as modern environmentalists often romanticize about the past. However, the people of this period were capable of planning elaborate subsistence regimes based on seasonal variation, for example, constructing sophisticated water projects that allowed them to irrigate crops and store fresh water for dry seasons. Rivers were diverted and dams built to better suit the needs of some and (sometimes) to purposefully weaken competitors.

Historians used to study the environment simply as a means of setting the stage for the

EASTERN MEDITERRANEAN AND MESOPOTAMIA, CIRCA 6,000 BCE

culture of interest to them. Now, historians have realized the profound importance that the environment plays on the development of any cultural group. Environment provides the immediate constraints and possibilities, initial problems that must be solved in order to survive, and resources that can allow people to thrive. In order to truly understand another culture, it is profoundly important to understand the environmental conditions in which it is found.

The first large organized polities developed in this period in regions that are environmentally stable and predictable yet require significant human intervention in order to make them habitable. Egypt and Mesopotamia are the earliest of these cultural regions. Both had been inhabited long before this period began, but both rise to prominence in this time. The Indus Valley civilization appears shortly after, and as with Egypt and Mesopotamia, this is a somewhat inhospitable land for hunting and gathering. Yet in all three of these regions, the major rivers are predictable and the soil is rich and productive, allowing for rich agricultural practices and healthy surpluses of food. These lands, although hot and barren outside of the river valleys, were able to support human life on a massive scale and were the first large civilizations.

—Kevin M. McGeough

The Nile Valley

In *The Histories*, the Greek historian Herodotus called Egypt “the gift of the Nile”; without the Nile, Egypt would be uninhabitable desert. Rains are rare in Egypt, so the population relies on the Nile River for fresh water not only for drinking but also for irrigating crops. Beginning in the Early Dynastic period, the ancient Egyptians altered the landscape of the Nile Valley in order to maximize the amount of land available for agriculture.

To understand just how important the Nile River is to Egypt’s survival, it is important to understand a little about the geography of Egypt. The Nile River runs from south to north. Over the course of millions of years, the Nile River cut a path through the high desert plateau from Lake Victoria in Kenya to the Mediterranean Sea, a journey of more than 3,000 miles. The erosive

forces of the river created cliffs on either side of the fertile Nile Valley, equivalent to a much longer and wider Grand Canyon. Every winter, the Nile River overran its banks and flooded much of the valley. When the floodwaters receded, highly fertile silt or mud was left behind. The deposition of this silt was thickest nearer the river, which caused the Nile Valley to be convex in cross-section. High silt banks retained the Nile, and the fields were below the level of the river. The terrain near the base of the high desert cliffs begins to rise again, and it is here that sand blown from the surrounding desert accumulates. These high areas are not flooded by the Nile and remain sandy desert, called the low desert plateau. The Nile River is not the only river in the Nile Valley. The Bahr Yousef (the Arabic term *bahr* means “river”) branches off from the Nile between the ancient city of Amarna and the present-day capital of Asyut and flows into a permanent lake called Birket el-Qarun. The area surrounding the lake, called the Fayoum, is highly fertile due to deposits of silt from the annual flooding of the Nile and made this region valuable in terms of agriculture. Near present-day Cairo, the Nile breaks up into several branches (as many as seven in pharaonic times and only two today) to form the fertile delta, or mouth, of the Nile River where it flows into the Mediterranean Sea.

In Paleolithic times, Egypt had much more rainfall, and the high desert plateau had grasslands that could support a large variety of animals (elephant, rhinoceros, giraffe, gazelle, antelope, etc.), which in turn sustained Egypt’s early populations. At some point in the Predynastic period (ca. 3250 BCE) Egypt became very arid, large animal species migrated or died off, and the early peoples were forced to turn to agriculture as their sole source of food.

With almost no rainfall in Egypt, farmers relied on irrigation to water their crops. The method of cultivation in ancient Egypt was called basin-irrigation farming. This involved creating small walls of earth in order to form a series of depressions in a field. These basins not only retained the floodwaters of the Nile, which watered the new crops, but also caught the highly fertile silt suspended in the water. Where a particular crop was planted depended entirely upon

► THE SHADUF—DRAWING WATER FROM THE NILE

The water-lifting machine that was used by the ancient Egyptians to raise water from a river or canal in order to irrigate their gardens is called a *shaduf*. Pronounced “sha-doof,” the word for this device comes from the modern Arabic and remains in use all over Egypt today. The ancient Egyptian term for *shaduf* is unknown, as the only evidence for it comes from illustrations on tomb walls.

The *shaduf* first was employed in Mesopotamia as early as 2370–2200 BCE, as indicated by a depiction on an Akkadian cylinder seal. The first evidence for the use of the *shaduf* in Egypt comes from drawings in the New Kingdom (Eighteenth Dynasty) tomb of Merire at Amarna. Prior to the New Kingdom, the ancient Egyptians used water jars suspended from yokes to lift water out of the Nile or canals.

The *shaduf* had a basic lever design consisting of a pole, the center of which rested on a fulcrum. The pole had a bucket attached to one end and a counterweight on the other. The *shaduf* required only one person to operate it, and because that person did not have to take time-consuming trips up and down the bank of the Nile (or canal), much more water could be lifted much faster than through the traditional yoke method. However, the *shaduf* was not efficient enough to be used as the only means of irrigating fields of summer crops. It was utilized primarily for vegetable gardens and orchards and to fill small pools for fish or fowl.

—Vanessa Smith

Villagers in Egypt use a *shaduf*, about 1910. (Library of Congress)

its available water source. Vegetables required constant watering, and gardens were placed near wells, canals, or the river so that they could be watered daily either by hand or with the *shaduf*, a simple water-lifting machine. Grain crops only needed a burst of water for initial growth and could be placed in fields that flooded but were at some distance from a continuous water source. Finally, levees and higher ground were planted with date palm trees whose roots were deep and did not require much water.

While most basins that were created by local farmers were small and relatively shallow, some basins were built at a monumental size. These huge basins, often built by kings, formed permanent artificial lakes 2,500–50,000 acres in area

and acted as insurance against a poor Nile flood, for if the annual flood was low, crop yields would be small, and starvation would follow. Artificial lakes could relieve some of the drought by the controlled release of some of the water through the canal systems to water crops.

Earthen walls, or levees, were also used to hold the inundation away from areas that the ancient Egyptians did not want to flood. Settlements in the Nile Valley were located on two different types of terrain: at the edge of the low desert plateau, which was unlikely to be reached by floodwaters, and on turtlebacks. A turtleback is a natural hill or high spot within the cultivation. The building of settlements on turtlebacks had three advantages, the most important

of which is that the floods would not wash the village away every year. Second, because the floods did not reach this land, it was unsuitable for agriculture, which made it perfect for towns. And finally, because the turtlebacks were within the cultivation, village farmers were close to their fields. The very nature of being within the floodplain meant that even a settlement on a turtleback could be flooded. Only levees could hold the waters back from homes, livestock, and grain stores.

As discussed earlier, the silt deposited in the Fayoum region made the lands around the lake important in the annual agricultural production of Egypt. However, sometime in the First Intermediate period, the Bahr Yousef became blocked with silt at the Hawara Channel (located at the place where the Bahr Yousef turns west and stretches into Birket el-Qarun) due to a series of unusually low inundations. In the Middle Kingdom, King Amenemhat I removed the silt and widened the Hawara Channel in order to restore and increase water flow to the lake. In so doing, a reservoir was created for those years when the Nile flood was poor and served as a flood escape for those years when the Nile flood was dangerously high. The Twelfth Dynasty rulers, therefore, had created an insurance policy against the unpredictable Nile floods. The Fayoum basin, with its permanent lake, would continue to provide food in case of drought and acted as a catchment in case the flood was too high, thus protecting valuable farmland in Lower Egypt. The importance of this area is emphasized by the fact that Senwosret II and Amenemhat III built their pyramid complexes here (Lahun and Hawara, respectively).

It was very important to the ancient Egyptians to know what to expect from any particular flood. The varying heights of the inundation determined how good a crop was. Too high a flood might ruin infrastructure and cause planting to be too late. A low flood meant that floodwaters did not reach as many fields, and fewer crops could be planted. The ancient Egyptians set up a series of nilometers up and down the Nile River that measured the height of the river. If a flood was going to be high, a warning might be sent upstream to let people prepare. Additionally, the Egyptians kept track of which lands

flooded at which height of the Nile. Using this data, the state could estimate the grain yields at harvest and could levy taxes appropriately. This meant that the value of a piece of land was based on its likelihood of flooding annually or intermittently.

The Mesopotamian Floodplain

Surrounded by mountains in the north and east and desert in the west and bounded in the south by the Persian Gulf, ancient Mesopotamia was shaped by its two rivers, the Tigris and Euphrates. These provided water for agriculture and daily life and were the main highways for communication. Major environmental differences divided Mesopotamia into two distinct regions, the northern plains of Assyria and the southern Babylonian alluvium. Further differences split Babylonia into a northern river plain (Akkad) and a more southerly delta plain (Sumer). These geographical contrasts were mirrored by cultural, political, and economic distinctions. Marshes divided Babylonia from Elam, the eastern alluvial plain and adjacent Zagros Mountains, a land whose history frequently intertwined with that of Mesopotamia. At times, cities and states beyond the desert and the mountains were also involved with Mesopotamia, while mountain and desert fringes were home to tribal groups who frequently raided their settled neighbors.

The surface geology of the Near East is mainly sedimentary limestone and sandstone, but volcanoes have also created outcrops of basalt and obsidian. Pressure from the Arabian shield in the west forced the adjacent lands to fold, forming the Zagros Mountains and depressing the intervening area, creating a trough in which the rivers deposited alluvium.

Between the marshlands and the latitude of modern Ramadi and Baghdad, where the Tigris and Euphrates come within 19.8 miles (32 kilometers) of each other, lies the alluvial region of Babylonia. Its agricultural prosperity depends on irrigation, since the scanty rainfall is quite inadequate to water crops and the rivers' annual inundation unhelpfully occurs around harvest time. The deeply incised and fast-flowing Tigris was difficult to harness for irrigation, and settlement along its course was largely eschewed. Farming therefore concentrated along branches of the slow-moving Euphrates, which watered a wide expanse of plain. The land to the east along the Diyala, a tributary of the Tigris, formed an extension of the Babylonian political and economic sphere; here both dry farming and irrigated agriculture were possible.

The alluvial river plain is almost flat, decreasing from a gradient of 1.8 inches per 1,093 feet (30 centimeters per kilometer) to just 3.9 inches (10 centimeters), producing a landscape in which the river divides into several meandering watercourses, and farther south in the delta plain below Hilla, it decreases still further to 1.18 inches per 1,093 feet (3 centimeters per kilometer). The meager gradient causes the Euphrates' branches to run sluggishly through the plains, depositing silts that gradually raise their beds and the surrounding banks so that the rivers flow on levees, which can reach 1.2–1.8 miles (2–3 kilometers) in width, raised above the surrounding plain. These provide a fertile and well-drained environment ideally suited for cultivation. Irrigation channels can be cut through the levee banks to divert water onto the surrounding land, using gravity flow. Willow, poplar, licorice, tamarisk, grasses, and rushes form dense thickets along the watercourses, providing food and shelter for wild boar and fallow deer.

Spring melting of snows in the distant Taurus Mountains, where the Tigris and Euphrates rise,

➤ CANAL MAINTENANCE AND CONFLICT

The creation of canals and dams could significantly alter drainage patterns; though often unwitting, at times the interference was malicious. Upstream communities sometimes channeled water to serve their own needs at the expense of communities farther downstream, creating a catalyst to conflict. Several kings diverted the Euphrates to starve hostile cities of essential water supplies or to destroy them by flooding, often with devastating long-term effects. For example, Sumu-El (1894–1866 BCE) of Larsa built dams to divert water from the rival kingdom of Isin, contributing significantly to its decline. But his own state, farther downstream, also suffered as a result, bringing famine. This failure in his primary responsibilities to his own people led to a popular revolt in which he was replaced by a commoner, Nur-Adad, who soon restored the canals to their original courses. Nur-Adad's son, Sin-iddinam, recorded that he and his father were assiduous in performing their duties to dredge the river and maintain the canals, work that was crucially important for the well-being of the state.

—Jane R. McIntosh

swells the rivers in April and May, causing them to flood their backslopes. Every few years they burst their banks and inundate a wide expanse of the alluvial plains, encouraging the Euphrates to change its course and multiply its channels. The arrival of floodwaters just when the crops are ready to harvest means that drainage and flood control are as important as irrigation.

Away from the narrow fertile strip along the rivers and canals, the land is dry semidesert mud. Here the perennial vegetation consists of scrubby, xerophytic species such as camelthorn and artemisia (wormwood), which in antiquity were more abundant. Overexploitation has resulted in erosion and desertification in many places. During the hot dry summer and early autumn (May to October), this is a bleak region inhabited by small elusive fauna—birds, burrowing creatures, and their predators, jackal and fox. The rains, although generally slight (rarely exceeding 5.9 inches, or 150 millimeters, per annum), transform this landscape in the winter and

spring, producing fast-growing grasses, flowers, and other herbaceous plants that provide seasonal grazing for domestic sheep and goats and for gazelle and, in antiquity, onager, preyed on by hyenas and lions. In places, low-lying hollows and relics of former watercourses allow water to collect, creating shallow lakes or seasonal swamps that attract wildlife, particularly birds including sandgrouse, teal, pelicans, geese, cranes, and sometimes flamingos and ibises.

Towns and cities clustered along the watercourses, each surrounded by fields and gardens, and the adjacent desert provided grazing. But the contrast between waste and fertile land hung on the availability of water. Prosperous settlements could suddenly be stranded in newly formed semidesert as their life-giving river moved elsewhere. The Babylonian landscape is littered with abandoned settlements, great tells rising in what is now the middle of nowhere. And the greater the investment in irrigation works, the more catastrophic the change.

Although often politically divided, the city-states of Babylonia were united by their environment, common problems, and solutions, promoting the growth of a common culture. Sharp ecological contrasts and significant geographical barriers divide this region from the surrounding lands: marshes to the east, and to the west a low rocky escarpment marking the frontier with the desert.

Elam and the Zagros

The Zagros foothills form a region of open woodland and grasses that enjoy warm dry summers and mild wet winters. The region skirts the low ranges that jut out from the Zagros; of these the most formidable is the Jebel Hamrin, a steep and rugged range rising to 656–984 feet (200–300 meters) that presents a major barrier dividing the lands of the north from the plains of Babylonia. The Diyala River cuts a pass through Jebel Hamrin and flows into the Tigris some 111.8 miles (180 kilometers) to the southwest. South of the Diyala, marshes divide the Babylonian plain from Susiana (Khuzestan).

Although Susiana is geologically part of the southern plain usually associated with the Mesopotamian cultures, it was culturally and economically quite distinct from Mesopotamia. Apart from marshes in the extreme south and an arid zone south of Ahwaz, the region lies within the area where rain-fed agriculture is possible. Five rivers rising in the Zagros, of which the Karun and the Karkheh are the most substantial, allow productivity to be increased by irrigation.

Cultivation was only a part of the farming economy of Susiana, where transhumant sheep and goat pastoralism has great antiquity. In winter, flocks grazed on the plains and foothills, covered in tamarisk, pistachio, jujube, and grasses, and in summer in upland pastures of the Zagros, where in antiquity there were widespread open forests (now largely denuded), mainly of oak and pistachio, interspersed with abundant herbaceous vegetation, home to herds of red deer, roe deer, wild sheep, and wild goat.

Susiana and the adjacent Zagros region became known to the Mesopotamians as Elam. Through history, Elam varied in extent, at times including Anshan, the mountains and coastal plain along the eastern side of the Persian Gulf. From the Zagros, Elam looked east across the Iranian plateau with which it often had close economic and cultural ties. To the west, routes around the northern and southern edges of the marshes gave access to Babylonia, by turns friendly or inimical to Elam; the northern pas-

sage also joined routes into Assyria, with whom Elam often had hostile relations.

The Diyala River, Elam's northern boundary, was one of the main access routes into the Zagros mountain chain, which rises to 2.2–2.4 miles (3,600–4,000 meters) in a series of steep terraces, well watered and lushly vegetated in antiquity. In places, patches of grass-covered soil along valleys or on hillside terraces give the opportunity for small communities to practice cultivation, although pastoralism has always provided the main way of life. The high Zagros offers rich summer pastures, and in the bitter winters grazing is found on the lower slopes or foothills on either side of the mountains. Three larger intermontane valleys—the Shahrizur, Rania, and Rowanduz plains—offer scope for more dense settlement, but the difficulty of movement through the Zagros meant that they were always home to tribal groups rather than larger political entities. From the Zagros, Assyria and Babylonia were frequently raided by groups speaking many languages, such as Hurrians, Gutis, and Kassites.

The Mediterranean

The Mediterranean Sea encompasses wide sections of southern Europe, Asia Minor, the Levant in West Asia, and vast regions of North Africa. The geographic attributes of these regions retain similar yet distinctive characteristics that have shaped the historical patterns, climate, and cultural and economic diffusion of this important world region. Debates among historians and geographers over whether or not there is a unified

Mediterranean world stems from studies that attempt to link the historical evolution of the region emphasizing the similarities of the adjacent cultures while minimizing the differences. Given the immense diversity of regions, cultures, and resources that surround the Mediterranean Sea, it remains a complex geographic area for study by scholars.

The geographic evolution of the Mediterranean region begins with the breakup of the supercontinent of Pangaea occurring over various millennia. The gradual dismemberment of Pangaea into various continents due to the process of plate tectonics led to the formation of the Tethyan Ocean in a gap created between the evolving modern continents of Europe and Africa. Scholars speculate that this ancient ocean had only limited access to the Atlantic Ocean and was subject to constant evaporation, leading to the formation of the characteristic salt beds on the floor of the Mediterranean Sea. The eventual opening of the Straits of Gibraltar allowed the constant flow of salt water into the Mediterranean, but it had already retained its signature salt beds formed in the previous period. As a boundary between tectonic plates, the Mediterranean basin is also characterized by volcanic activity and earthquakes. Various mountain ranges were formed as a result of the collisions between the African plate and the European plate, such as the Caucasuses, the Apennines, and the Alps. Volcanic activity such as the massive eruption of Mount Vesuvius that caused the destruction of Pompeii in 79 CE is a testament to the cataclysmic effects of tectonic processes.

The economic resources of the Mediterranean region were formed in this early period of geological processes, which formed the various mountain ranges and shaped the contours of the coastlines. The flow created by igneous belts moving through rock strata moved mineral formations throughout the rock formations and mountain ranges, leading to a rich diversity of elements. Oil as well as ores such as copper, lead, and zinc are among the various deposits in the Mediterranean, which in turn affected the cultures and civilizations that extracted and processed them. The large deposits of copper in Asia Minor were used by the ancient Hittites in the production of bronze artifacts (nineteenth to

twelfth centuries BCE). The formation of limestone allowed for its usage as a primary construction material, which characterized the architecture of various urban areas around the Mediterranean. Oil reserves in adjacent areas also formed in this early period, which are now evident in the immense oil production in the Middle East and natural gas reserves around Italy.

The Mediterranean climate, generally characterized by cool summers and temperate winters, actually differs from region to region according to its location and other factors that contribute to climatic shifts. Precipitation also fluctuates accordingly and is characterized by long periods of drought followed by long bouts of rain that in turn lead to flooding, particularly in low-lying regions such as Venice. The heavy months of rain, typically in the winter, are sometimes followed by long dry periods, which have a greater affect in the more arid areas such as southern Spain and Algeria. The formation of anticyclones in the western Mediterranean also creates unstable weather conditions, which have led to high winds and extreme levels of precipitation. In the winter months, extreme temperatures with the chance of snows are possible even in arid North Africa. In the summer months, extreme heat can cause death in some southern European cities. The climate also affects the type of agricultural practices and crops particular to the various regions. Olives, wine grapes, pistachios, and figs characterize the Mediterranean region, each crop adapted to a unique region's distinct weather pattern. For example, Italy, Greece, and southern France are historically known for their olive oils and fine wines.

Of the various civilizations that emerged out of the Mediterranean region, none have garnered more fame in the historical profession than the ancient Greeks and perhaps to a lesser extent the ancient Phoenicians. Ancient Greek civilization emerged from the cultural diffusion that characterized the eastern Mediterranean as a result of the growth in trade and the expansion of political control of the Aegean by various Greek city-states. Prior to this, Minoan civilization (1200–1250 BCE) had flourished on the island of Crete and manifested itself at Knossos. In the Minoan kingdom, early vestiges of what would later evolve into Greek culture began as an example

of the seafaring skills that people of the region had developed. These capabilities for seafaring and maritime technology allowed the ancient Greeks to colonize the Mediterranean region and expand their economic ties with other ancient civilizations. The destruction of Minoan civilization (1760 BCE) is speculated to have been caused by an earthquake or by invasion, but the subsequent period includes the growing diffusion of Greek culture throughout areas surrounding present-day Greece, southern Italy, Spain, and much of Asia Minor (Turkey). The ancient Phoenicians (2000 BCE), also a seafaring people, traded and colonized areas in Spain and Carthage (North Africa) from their home bases in Canaan (Palestine/Lebanon). The diffusion of Hellenistic, Roman, and later Byzantine and Islamic cultures followed the trade links and sea routes established in the period of the ancient Greeks and Phoenicians. Much of this cultural diffusion is apparent in the architecture, religions, and languages of the ancient and later periods of the history of the region.

The Environment of Ancient India

The Indo-Pakistan subcontinent consists of three main geomorphological regions: Peninsular India, which juts out into the Indian Ocean in a triangular shape; the extrapeninsular mountain system, which separates the subcontinent from the rest of Asia; and the alluvial plains of the Ganges and Indus rivers. The inhabitants of India early in the period 4000–1000 BCE were con-

centrated in the alluvial plains associated with the Indus River and are referred to as the Indus Valley civilization or the Harappans (after one of the two largest excavated sites). By the end of the period 4000–1000 BCE these settlements had been abandoned, and people (the bearers of Vedic culture) had settled along the Ganges River.

The Indus Valley civilization was spread over a relatively large geographic region. The two largest sites, Harappa and Mohenjo-daro, are about 388 miles (625 kilometers) away from each other. Both are located along the Indus River or its tributaries. Smaller settlements were located all along the Indus River. The Indus River flows south into the Arabian Sea, fed from tributaries that originate as snowmelt in the Himalayas. The river carries a vast amount of silt with it, which causes the riverbed to get higher and higher, leading to sometimes disastrous flooding but also providing a rich source of agricultural soil. The many tributaries in this region facilitated transportation in this area.

In ancient times another river, the Ghaggar-Hakra (probably identified with the Saraswati River mentioned in Vedic texts), was equally if not more important for the development of this society. Now mostly dried up, this ancient river ran parallel to the Indus River. Unlike the Indus, the Ghaggar-Hakra does not seem to have been fed by melting snow in the Himalayas but instead relied on rainfall during the monsoon season, a less stable source of water. Most Indus Valley sites are actually located along what would have been the course of this river, including the large site of Ganweriwala that has yet to be excavated. Thus, the designation of Indus Valley civilization may be something of a misnomer.

The Indus Valley civilization was surrounded by natural boundaries. To the north, the mountain ranges of the Himalayas were nearly impassable, thus preventing contact with East Asia. To the east was the Thar Desert; as the climate became more arid to the east, human settlements disappeared. To the south was the Arabian Sea, where evidence of trade and trade routes have been identified. Contact with other civilizations also occurred throughout the west and northwest. The region to the west, known as Baluchistan, encompasses parts of modern Afghanistan, Iran, and Pakistan. While mountainous and hilly,

➤ THE GHAGGAR-HAKRA RIVER

The earliest excavators in India concentrated their excavations and surveys near the Indus River, rightly thinking that given the climate, substantial human settlements must have been located near a major river or tributary. Subsequent investigations demonstrated that most settlements had been located along an ancient river, called the Ghaggar-Hakra, running parallel to the Indus. This river had gradually dried up during 4000 BCE–300 CE. As it dried, it split into numerous streambeds. This process seems to be documented in Vedic literature. The Ghaggar-Hakra in these sources is called the Saraswati and is also personified as a goddess. The Rig Veda and the Mahabharata both attempt to explain the constantly shifting nature of this river and document its eventual disappearance.

—Kevin M. McGeough

many passes (such as the Khyber Pass) allowed movement between these regions; there is substantial evidence for contact with the civilizations to the west.

The climate of ancient India was probably not so different from the climate of India today. The principle location of the Indus Valley civilization receives less than 8 inches (200 millimeters) of rainfall annually, and thus agriculture must have depended on the Indus overflowing its banks and on irrigation schemes based on this seasonal pattern. From June to September the monsoons would bring this rainfall, more so in the north. By November, winter conditions set in, lasting until March, when the harsh summer weather began. Although uncomfortably warm, the climate and geography of the alluvial plain were (and still are) well suited for human habitation.

China—An Ecology of Diversity

From east to west China rises in a stair-step fashion to the Tibetan plateau. Almost 70 percent of the country is higher than 3,200 feet, more than 40 percent is higher than 6,000 feet, and a large part of the Tibetan plateau is higher than 16,000 feet above sea level. Even in the lower-lying areas within 500 miles or so of the coast, China has much rugged terrain, especially in the southeastern provinces such as Zhejiang, Jiangxi, Fujian, Hunan, Guangdong, and Guangxi. China's major rivers rise in Tibet and take an easterly course as they head to the sea, carving deep canyons as they descend the heights. Much of China's early history is closely connected with the geography of its rivers.

The home of early Chinese civilization lies in northern China, in the vast drainage area of the Yellow River valley. In fact, no other physical feature in early Chinese history played as prominent a role as the Yellow (or Huang) River, which serves to this day as a supporter of agricultural civilization. About 2,700 miles in length, the Yellow River has built a vast floodplain from centuries of silt deposits. In fact, the silty loess sediments of the Yellow River played a role in later Chinese history unlike any other physical feature on the Chinese landscape. The river's frequent flooding created a continuing problem for Chinese rulers, who had to build dikes and clear sediments in order to keep the river on course. Indeed, the river has jumped its banks, broken its dikes, and changed course many times in the past 2,000 years, causing great devastation as it surged to the sea and giving the river its title as "China's Sorrow."

China's southern river, the Yangzi or Changjiang, is 3,200 miles long and less prone to flooding than the Yellow River. Even so, heavy rainfall on its vast watershed can quickly raise water levels to enormous heights. It too has caused frequent devastation throughout Chinese history. The Yangzi River represents the geographical features of the south in other ways as well. Its vast network of tributaries is reminiscent of what was called in early times the "marshy southland." In fact, one of the most powerful differences between northern and southern China is the wetness of lands in the Yangzi River valley and

southward. The Yangzi creates the possibility of easy rice cultivation (grains such as wheat are far more prevalent in the arid north), fishing, and river trade.

One historian, examining Chinese dynastic histories over two millennia, noted that flooding or drought accounted for almost 15 disasters a decade throughout Chinese history. Clearly, the geography of this complex landmass has played a significant role in the lives of its people. This is also the case in the matter of rainfall. We can draw a line from Manchuria in the northeast down to the far southwest of China Proper to mark the rather dramatic differences in rainfall from northwest to southeast. In fact, we can follow that diagonal line to see that the more arid northwest regions support a vastly different kind of economy than the more lush southeast. The peoples who lived for generations in the arid regions beyond the Great Wall were never closely, or continuously, connected to the people and territories most often covered in Chinese civilization narratives, yet these nomadic peoples played an enormously important role in later history. The wetter regions of the far south also were not fully integrated into Chinese culture until the beginning of the Common Era, indeed some only within the past 1,000 years. Until relatively recently, exceedingly wet or dry regions had rather tenuous connections to the mainstream political and cultural life in China Proper, at least in its early history.

China is also known for its vast and complex mountain ranges, many of which have figured in political history and, for that matter, in thousands of pages of poetry written over three millennia. Most symbolic of all are what are called the "Five Cardinal Peaks" in the north, denoting each of the "five directions" so important to Chinese cosmological classification: north, west, south, east, and center. The major mountain ranges form great physical barriers that protected warring states such as the Qin in the third century BCE, gave respite to rebel groups harassed by government troops (as in the case of the White Lotus rebels in the late eighteenth century), or even sheltered Mao's Long March in the 1930s.

Finally, there is China's coastline, which makes up 8,700 miles of China's border. Until the nineteenth century the coast did not represent a

significant vulnerability to external threat; in fact, coastal defenses were something of an afterthought throughout Chinese history. To be sure, Japanese and other travelers arrived at Chinese ports, and coastal trade was present from early times. Still, China scarcely worried about its coastal borders and spent little effort exploring the possibilities beyond the coasts until the British arrived with opium in the eighteenth century. Aside from a few missions initiated by the First Emperor of the Qin and a brief three decades of naval exploration as far as Africa in the fifteenth century, life beyond 30 miles of the coastline held little appeal to most prominent actors in Chinese history.

Rivers, mountains, coastlines, and other geographical features figure prominently in any narrative of China's past. It is important not to think of them as causes of historical change in and of themselves. Yet their very structural significance, in terms of rainfall, flooding, mountainous respite, and coastal possibility, figured greatly in the choices that historical figures made (or failed to make) in light of these enormous geographical features.

Jomon Culture

The Jomon period covers more than 10,000 years of Japanese history from about 11,000 BCE to about 450 BCE. There were probably significant societal and technological changes during this period. We also know, from pottery styles and other evidence, that there was regional variation as well. However, we can still make some reliable generalizations about Jomon culture. The Jomon people(s) were hunter-gatherers but with

➤ JOMON AND THE JAPANESE LANGUAGE

Though written Japanese is heavily dependent on Chinese (the Japanese Kanji characters) and has some similarities of grammar to modern Korean, it is not clearly related to either. Where then does Japanese come from? One answer, which is popular in Japan, is that it is a direct descendant of the Jomon language. This is also taken to mean that the Jomon people are the ancestors of the modern Japanese and thus that the Japanese have always lived in Japan. Another explanation is that the Japanese language is a mixed or contact language with elements of Jomon alongside the (presumed) Korean-type language of the Yayoi period. Chinese cultural influence was later added. It is probable that Japanese is the descendant of a now extinct language spoken in southern Korea, especially in the old kingdom of Paekche.

—Michael Thompson

the difference that they settled in one place for long periods. By investigating these sites, we can reconstruct Jomon culture at least as it was lived at a particular place and time.

The word “Jomon” means “corded or straw rope,” which is an element used in their pottery decorations. This simple fact actually tells us a lot about Jomon culture. First, they had a high level of artistic development. These pots were not just useful; they were decorative too. Second, they indicate the presence of specialized craftsmen, which in turn means a complex society where people can be divided up by specialization. Last, their size and complexity show both how settled the Jomon were and the fact that people were willing to purchase/obtain costly articles. The Jomon people also used precious stones such as jade and obsidian. Archaeologists have also found that Jomon people were careful in their burial customs and buried grave goods (arrowheads, ornaments) with their dead. This probably indicates some kind of cultural belief in the afterlife where these items could be used. In their settlements they also built large mounds, which are associated with a number of small ritual artifacts indicating religious ceremonies of some kind. There are also a number of

small female statues that were probably connected with fertility practices.

A complex society with social specialization and religious practices might mean people (priests) who had charge of these practices. However, we have no evidence that this was the case. The surviving Ainu people of Hokkaido, whose connection with Jomon is unclear, seem to have continued with a lifestyle similar to that of Jomon. In Ainu culture there are ritual specialists (shamans) responsible for religious practices, but they have other occupations as well. This may have been the case with Jomon. In various parts of mainland Japan and Okinawa there is a tradition of shamans as well. In most cases these are women, and that may have been the case for Jomon as well. The ethnic continuity of Jomon with modern Japanese is a contested subject. Cultural continuity is an even more difficult area for scholars.

In terms of material culture, Jomon depended on natural resources to survive. They seemingly had quite a varied diet (fish, meat, fruit, and nuts), and some scholars believe that they may even have made fruit wine. They traded between communities so that they were not just dependent on local food. They also made and used salt and preserved food. Their houses were most commonly pit dwellings with sunken floors and a roof of some natural material. These houses were not very big, averaging about 39 feet (12

meters) in floor space. They also had larger long-houses that probably served as community buildings, indicating a high degree of social cohesion and maybe decision making. While there are many things we do not know about Jomon culture, what we do know is enough to give us a general picture. Jomon culture was innovative in many ways, though their environmental impact was very limited.

Europe—Natural Boundaries

The landscape and climate varies significantly throughout Europe, and numerous topographic and ecological boundaries present obstacles to the movement and interaction of humans. Major natural boundaries include mountains, seas, and deserts, the former two of which are particularly relevant to Europe. Unlike North America and Africa, Europe has a significantly long east-west axis, meaning that a number of regions at the same latitude experience similar temperature ranges, seasonal variations, and levels of precipitation. This principle largely holds for all of Eurasia and partially explains the rapid spread of domesticated plants and animals in Europe. Thus, even though there are obstacles for travel between these regions, the similar environments along this east-west axis allow plants and animals that are moved along this axis to readily adapt to their new environment.

Prominent mountain ranges in Europe include the Carpathian Mountains, the Caucasus, the Alps, and the Pyrenees. The topography of these systems has shaped and constrained the relationships of prehistoric societies for thousands of years.

During the Early Bronze Age, for instance, significant cultural differences existed between populations to the north and south of the Carpathian Mountains. Whereas fortified settlements

► TEMPERATE FORESTS AS NATURAL BOUNDARIES

Temperate forest cover influenced the development and spread of farming in Europe. In Mesolithic Europe, before the emergence of sedentary agricultural communities, hunter-gatherers frequently migrated along coastal regions in order to maximize the diversity of resources they could exploit. Dense tree stands reduced available grazing space for game and made long-distance travel difficult. With time and increased dependence on agriculture, humans required open-field systems. Although forested regions were occasionally cleared for agriculture, most populations were forced to exploit naturally open areas away from woodlands.

—Noah V. Honch

and flat-grave cemeteries were the norm in the south, meager rural settlements and large earthen burials mounds typified the north. Although metal ore sources were commonly exploited in the Carpathian Basin, the mountains drastically influenced the orientation of trade networks in central Europe. This also occurred in the Alps; in the Mitterberg region, for instance, local deep valleys frequently limited contact between autonomous metal-producing communities. Although transalpine travel was difficult it was certainly possible, as the diverse origins of preserved artifacts with the Tyrolean iceman clearly attest. The Pyrenees may have deterred terrestrial travel between France and Spain in antiquity, but they were probably bypassed quite easily by sailing along the Mediterranean or Atlantic coasts.

Large water bodies were also formidable boundaries in Europe. The Mediterranean exists as a boundary in the sense that it defines the southern limits of Europe. In antiquity, it was a hindrance to travel and trade with the infrastructure because sailing was poor. By the Bronze Age, Bell-Beaker groups were present in southern Portugal, suggesting that sea travel was available quite early. By the time of seafaring Mycenaeans and Phoenicians, the Mediterranean coast essentially defined the primary routes of trade and migration. Other water bodies, while not completely inhibiting movement, effectively slowed the diffusion of people and ideas. The English Channel, for instance, delayed the arrival of major domesticated plant and animal species to England, which occurred one to two millennia after most regions in central and western Europe.

Mesoamerican Geography

"Mesoamerica" is a term used by archaeologists and anthropologists to refer to Mexico and neighboring countries in Central America in the period prior to European contact. While the peoples who inhabited this region prior to the arrival of Europeans were incredibly diverse, archaeologists see a number of cultural connections that distinguish ancient Mesoamericans from ancient North Americans and South Americans. Thus, the ancient civilizations of Mexico, Guatemala, Belize, El Salvador, Honduras, Nicaragua, and Costa Rica may all be deemed Mesoamerican.

Despite the small size of this region, this is one of the most environmentally diverse regions in the world. Within this area, the climate vacillates between extremes of dryness and wetness and of hot and cold. High mountain ranges cede to vast lowlands. This diversity of ecological zones brought both possibilities and constraints to the people of ancient Mesoamerica. It is not surprising that there was considerable diversity in approaches to subsistence practices. Numerous active volcanoes dot the region, and much of Mesoamerica is susceptible to earthquakes. While active volcanoes bring with them particular dangers, they also provide fertile soils for agriculture. Obsidian is another gift of volcanic activity; it is a type of stone that the ancient Mesoamericans would use to create extremely sharp implements.

A useful distinction to keep in mind when considering the geography of Mesoamerica is that between highlands and lowlands. The highlands

Sierra Madre mountains in present-day Mexico. (Jesus Eloy Ramos Lara/Dreamstime)

➤ TIERRA FRÍA, TIERRA TEMPLADA, AND TIERRA CALIENTE

Differences in rainfall and altitude define three distinct climatic regions of Mesoamerica: *tierra fría* (cool lands), *tierra templada* (temperate lands), and *tierra caliente* (hot lands). The *tierra fría* climate zones are arid and dry and are located along the northern coasts and in the northern highlands. These cold zones are the highest in altitude, higher than 6,561 feet (2,000 meters). In these areas,

nights are cold, and frost is a possibility. The *tierra templada* zones are located at a lower elevation (about 3,280 feet, or 1,000 meters). In most areas there is sufficient rainfall for maize agriculture. The *tierra caliente* zone roughly equates with the lowlands, which are extremely humid.

—Kevin M. McGeough

consist of two general regions: the Sierra Madres and the highlands of Guatemala and Chiapas (a state in Mexico). The Sierra Madres are located in the northern areas and project wedge-shaped down into the south. Their height is substantial enough to interfere with cloud formation, and thus this is a particularly dry part of Mesoamerica. In some parts of the highlands, agriculture was possible when irrigation methods were utilized.

The lowlands in the north are thin coastal strips that gradually increase in width as they move farther south. The lowlands are environmentally diverse, moving from tropical rain forests in the south to arid brush forests in the

north. Very wet summers contrast with very dry winters, although not all regions become dry in the winter months.

Location relating to the Isthmus of Tehuantepec is another geographic distinction that led to important cultural distinctions. This is the location of the short land distance between the Pacific Ocean and the Gulf of Mexico; the continental landmass constricts considerably here. To the west of the isthmus were highland mountain regions. To the east, rain forests predominated in both highland and lowland areas. It was at this isthmus, at the confluence of two distinct habitat zones, that Olmec civilization arose.

■ Introduction: Climate Change and Natural Disasters

Archaeologists are able to reconstruct the environment and changing climate patterns in the period from 4000 BCE to 1000 BCE using a variety of scientific means. What is often less certain for these scholars is what exactly caused these changes and how much of an impact these changes may have had on ancient societies. Since human activities—especially deforestation, agricultural practices, and water management—also play a role in climate change in this period, identifying causes and effects can be particularly difficult.

Evidence for dramatic events and large-scale natural disasters comes in a number of forms. Ancient records (both written and artistic) sometimes refer to earthquakes, unseasonable weather, volcanic activity, and storms. The results of these disasters can often be recovered archaeologically, such as the volcanic ash that covered the village of Akrotiri or cracks from seismic activity found in buildings. Drawing conclusions about the long-term effects on the humans who experienced these disasters is not as straightforward. For example, we are really unsure of how dramatic an impact the eruption of Thera had on agricultural practices in the surrounding region. Did it amount to a few days of strange weather? Or did it force a transformation in agricultural practices by altering the climate patterns of the eastern Mediterranean?

Less dramatic evidence for climate and climate change is also available to archaeologists. Information about ancient temperatures is preserved in the sediments of the ocean floors. Scientists can take what are called core samples (long but thin columns of sediment) and study

the variations (in the remains preserved within the cores) of one-celled organisms called foraminifera that are readily effected by temperature fluctuations. Similar methods can also be used on ice cores. From the data collected using these and similar techniques, it is possible to reconstruct ancient wind and precipitation patterns.

Changes in the landscape can also be reconstructed by archaeologists. For the cultures of this period, changes in river flow are particularly important, given the large percentage of people who lived near the major river systems (i.e., the Nile, the Tigris and Euphrates, and the Indus River). The Indus River, for example, carries a significant amount of sediment that it deposits as it flows. These deposition processes lead to minor variations in the course of the river that, when taken over hundreds of years, add up to very substantial changes.

Pedologists (people who study soils) can also contribute to the reconstruction of the ancient climate. Of course, archaeologists are very interested in soil (since most archaeological sites are covered by it!), but pedologists provide further specialized information about changing weather patterns. They can immediately tell if the soil at a particular site was deposited by humans, water, or winds and can also determine the subsequent erosion processes. Certain types of soil are only deposited under certain kinds of climatic conditions. So, for example, if loess soils are found at a site, it is certain that the site experienced a period of cold and dry climate, as these are the only conditions in which such soils can be deposited.

—Kevin M. McGeough

The Drying of the Sahara

Of the past 10,000 years, one of the most readily observed environmental changes has been the desertification of the Sahara. By about 3500 BCE, the process of desertification had begun of what had once been if not lush verdant land then at least a temperate landscape. By about 700 BCE, the Sahara had come to look like what it does today, a vast swath of marginally habitable territory with minimal precipitation. By this time, the Sahara had become the largest desert in the world, spanning an area of close to 3.5 million

▶ WHAT EVIDENCE EXISTS FOR RECONSTRUCTING THE DESERTIFICATION OF THE SAHARA?

The first European explorers of the Sahara were struck by rock paintings and pictographs depicting diverse animal and plant life that were ill-suited to an arid climate. Archaeological exploration further suggested that in order to support the human habitations in evidence, at some point the Sahara could not have been a desert. Geological research has clarified the situation, and although there are still numerous questions about the history of the Sahara, the situation is far better understood. Sedimentary research is less accurate here than in other areas of the globe because of the constantly shifting sands in the Sahara and problems particular to the geology of the region, so geographers have had to rely on other types of evidence to reconstruct Saharan climate history. Deep-sea cores taken downwind of the northeasterly winds that pass through the Sahara show that starting around 700 BCE the erosion of soil and sand (blown into the sea by these winds) increased dramatically. Likewise, lake sediment and geochemical analysis help reconstruct the changing nature of lake and lakeshore environments. Pollen analysis allows scholars to learn the relative proportions of different types of plants at different times. Since certain plants are better suited to some climates than others, charting the shifting patterns of vegetations allows scholars to chart shifting temperatures and climate patterns. New approaches to modeling complex phenomena have allowed scholars to better study how these and other factors interacted and were part of the creation of the Sahara Desert.

—Kevin M. McGeough

square miles, almost the size of the United States. It now encompasses all of North Africa and is bordered on the south by the Sahel, a stretch of semiarid tropical savanna that divided Africa into Saharan and sub-Saharan ecozones. Given its massive size, it should not be surprising that there are significant environmental variations throughout the Sahara and numerous distinct ecological regions. Despite this diversity, only limited human inhabitation has been possible through much of the desert since the Sahara dried up.

Before 11,000 BCE, the Sahara was an arid region much like it is today. But between 11,000 BCE and 3500 BCE, North Africa experienced a period of wetter conditions that allowed for a variety of human inhabitations of the region. This humid period was brought on by monsoons, which are caused by air heating over land. The hot air rises and draws in cold moist air from large bodies of water nearby, which in turn causes substantial levels of precipitation. These monsoons provided stable water resources to North Africa until slight variations in the earth's orbit (effects of which interacted with the earth's atmosphere and vegetation) pushed the monsoons farther south.

Without the seasonal monsoons, North Africa lacked stable water sources other than the Nile (which has its source far enough south to still be fed by monsoons). That is not to say that precipitation stopped altogether in North Africa; rather, the amounts of precipitation stopped being of sufficient quantities and of sufficient duration to sustain a nonarid environment. From about 3500 BCE until 700 BCE, the Sahara underwent numerous transformations related to this shift in climate patterns. Freshwater lakebeds became saltwater lakes or salt flats (what are referred to as *sabkhas* in Arabic), a process that may have begun as early as 4200 BCE in some areas. Since the rivers had dried up, the only method of output for these lakes had become evaporation into the air, meaning that large quantities of salt were left behind in the lakes and not removed by other hydrological processes. Flora and fauna not adapted to saltwater could not survive in this environment and were replaced by those that could. Likewise, vegetation not adapted to semiarid conditions also could not survive;

from 3500 BCE to 700 BCE paleoenvironmental evidence documents the death of tropical trees and plants and the gradual decline of grasses. Around 700 BCE, desert plants had fully taken root in the Sahara. At this time, precipitation levels had become hyperarid, meaning that less than 20 inches (500 millimeters) of rain fell each year.

Along with the decline in precipitation and the disappearance of vegetation, the Sahara also experienced a change in wind patterns. By about 700 BCE, the speed of winds increased, and powerful northeasterly winds came to dominate the weather year-round. These powerful winds combined with the lack of vegetation to cause severe erosion. With no plants to hold down the soil, the winds blew loose the soil and deposited it as sand dunes throughout the Sahara. Since these winds are powerful, frequent, and year-round, the dunes in many parts of the Sahara have been constantly shifting ever since.

Contemporary scholarly consensus holds that humans did not cause these particular environmental changes. However, human utilization of the Sahara changed dramatically because of them. Archaeologically, this is evident in gradual material culture and settlement pattern changes between about 3500 BCE and 700 BCE. As lakes became saline, lakeside settlements were abandoned in favor of seasonal oases and river valleys. In some of the larger oases, semisedentary life was possible, based on small-scale plant domestication. For the most part, however, those who chose to live in the Sahara had to adopt mobile lifeways. With the adoption of these highly mobile lifeways, the people of the Sahara adopted material culture that was better suited for constant transport. Outside of Egypt and larger coastal settlements, mobile lifeways became the most common.

The Sahara Desert continues to expand southward, but in contemporary times this is caused primarily by human factors. Deforestation in the Sahel (primarily for timber to be used as fuel) has led to erosion and desertification.

The Eruption of Thera

Thera (also known as Santorini) is a small group of islands in the southern Aegean Sea, just north of Crete. The islands are arranged in a circle around a caldera (a large crater) that resulted from the eruption of the volcano there. Although scholars are certain that the volcano erupted during the Bronze Age and are relatively certain about what happened when the volcano erupted, there is considerable controversy about the exact date of the eruption and the consequences of the eruption for the civilizations of the eastern Mediterranean region. Since the effects of the volcanic explosion should be identifiable throughout the region, the eruption of Thera should act

View of the caldera, Santorini, Greece. The caldera was formed by the massive eruption of a volcano on the island. The eruption and ensuing aftermath probably caused the end of the Minoan civilization on the nearby island of Crete. The date of the eruption is debated by scholars and this uncertainty poses significant problems in the chronology of the ancient Mediterranean and Near East. (iStockPhoto)

➤ DID THE ERUPTION OF THERA DESTROY THE LOST CIVILIZATION OF ATLANTIS?

Pseudoarchaeologists have made the spurious claim that the lost city of Atlantis, as described by Plato in two of his dialogues, was destroyed completely by the eruption of Thera. There is no evidence to suggest that Atlantis ever existed let alone that it was destroyed by this eruption. This suggestion was first offered by Spyridon Marinatos (a legitimate archaeologist), who excavated the village at Akrotiri destroyed by the eruption of Thera. He argued that Plato's account was based on an earlier story about the collapse of Minoan civilization and attempted to explain the discrepancies between the details provided by Plato and the details of Minoan culture as ancient translation errors. Most scholars remain unconvinced of this theory, understanding Atlantis as a fictional city imagined by Plato for didactic reasons. However, documentaries and Internet sites devoted to this theory proliferate because stories of Atlantis make for interesting entertainment.

—Kevin M. McGeough

as a chronological anchor for eastern Mediterranean chronology. Because of this, identifying the precise date of Thera's eruption is of considerable importance.

Thera did not erupt without warning. While the village of Akrotiri was completely covered by volcanic material, no bodies were actually found in the village, suggesting that the inhabitants had fled before the eruption. When Thera did erupt, the event could have lasted a few days given the intensity of the eruption. This was a Plinian eruption, characterized by a plume of pumice and volcanic material 27 miles (35 kilometers) high being ejected into the air. So much magma was removed that the volcano itself collapsed, leaving the caldera that makes the island chain distinctive today. The eruption was intensified when the Aegean Sea flowed into this crater; the water running over the exposed vent resulted in considerable steam. A tsunami likely hit the Cretan coast, although the degree of damage that this would have caused is disputed. Distant observers would have experienced storm-

like conditions and periods of darkness, atypical of the time of day. It would have been quite frightening.

The longer-term consequences of the eruption of Thera are unclear. Scholars generally agree that the amount of particulates ejected into the stratosphere would have resulted in a noticeable reduction in world temperatures. How much impact this would have had on worldwide civilizations is less clear. Would it have been enough to harm agriculture and force people to find new subsistence practices? Could the environmental changes have been severe enough to cause a number of civilizations to collapse? Or would it merely have been cooler than expected? Finding answers to these questions is very difficult. Maximalists argue that the Minoan civilization was severely disrupted (if not destroyed) by the eruption and that the other cultures of the eastern Mediterranean suffered varying degrees of collapse. Minimalists argue that the Minoans suffered through a few unpleasant days but were relatively unaffected since most of the volcanic material would have landed to the east of Crete.

Much of the problem with determining the extent of the effects of the Thera eruption is caused by the uncertainty regarding the date of the event. This uncertainty surrounding the date makes it difficult to establish correlations between the eruption and subsequent historical events. There are two ranges of dates that are most likely: 1550–1500 BCE, based on archaeological evidence, especially from Egypt, and 1627–1600 BCE, based on scientific dating independent of archaeological considerations.

The archaeological evidence is based on a number of factors and taken without the scientific evidence seems relatively reliable. The village of Akrotiri, which was covered by volcanic debris, contains material culture that can be associated with the Late Minoan IA period (LMIA) on Crete. Syro-Palestinian pottery dating to the Middle Bronze Age II period (MBII) was also found at Akrotiri, which is found at other LMIA sites in Crete as well. LMIA material culture from Crete is also found in Egypt in well-dated contexts. Egyptian dates have been reconstructed by scholars based on historical records of astronomical observations, radiocarbon dates, and

synchronisms with other regions. Generally, Egyptian chronology in this period is not seriously contested except when considered in relation to the scientific evidence for the eruption of Thera.

The scientific evidence for the eruption of Thera suggests that the volcano erupted about 100 years earlier than does archaeological evidence. Ice cores from Greenland show that there was a volcanic event within 20 years of 1644 BCE, although more recent analysis suggests that this may not have been the Thera eruption. The analysis of tree ring growth indicates that there was a temperature drop around 1629–1628 BCE, although once again this does not have to have been caused by Thera. Radiocarbon dates from various areas around the eastern Mediterranean provide more compelling evidence, suggesting dates for the eruption of 1660–1600 BCE. Recent radiocarbon dating of an olive tree found beneath the lava flow at Thera provided a date range of 1627–1600 BCE. This evidence is not compelling, however, since volcanic activity can cause discrepancies in radiocarbon dating. If this scientific evidence does in fact point to an earlier date for the eruption of Thera, most of the chronologies of the eastern Mediterranean need to be reevaluated. At the present, the archaeological evidence for an eruption date of 1550–1500 BCE seems most acceptable.

Volcanic Eruption and the Collapse of Akkad

The sudden collapse of the Akkadian empire at the end of the reign of Shar-kali-sharri (ca. 2223–2198 BCE) has long been attributed to the in-

herent instabilities of its administrative and economic systems, the internal pressure generated by the persistent revolts of its conquered city-states, and the external pressure applied by nomadic groups on its borders. In 1993, however, archaeologist Harvey Weiss suggested that the Akkadian empire fell as a direct result of the abrupt aridification of the Habur region (in northern Mesopotamia) following a volcanic eruption in 2200. With the loss of the Habur's productive dry-farming land—controlled and reorganized by the empire to help meet its agricultural needs—and the population pressure imposed on southern Mesopotamia by the refugees from that region, the Akkadian economy rapidly crumbled. Although kings of Akkad continued to reign until around 2159, following a brief interregnum after Shar-kali-sharri's death the territory over which they ruled was drastically reduced, comprising little more than the environs of Akkad and possibly the Diyala region.

While excavating Tell Leilan in the Habur River basin, Weiss and his team discovered a three-foot (one-meter) soil stratum so arid that even earthworm activity had diminished. This stratum, immediately overlying a .2-inch (.5-centimeter) layer of volcanic debris, was dated from circa 2200–1900 and was devoid of artifacts, indicating its abandonment during that period. An examination of other sites in the vicinity, including Abu Hgeira 2 and Abu Hafur, revealed a similar drought layer to that at Tell Leilan, and the general abandonment of many sites on the Habur Plain during this period suggested that a broad regional rather than local phenomenon was responsible. Weiss indeed speculated that the aridification of the Habur Plains and the subsequent collapse of the Akkadian empire resulted from a possible global climate-changing event that triggered simultaneous instability throughout the Near East and also in Egypt, the Indus Valley, and the Aegean. This drought was unlikely to have been precipitated by the preceding volcanic eruption; while volcanic activity may have short-term global effects, these are measured in years rather than decades or centuries. Current research is focusing on alternate causes of such climate changes, such as a shift in tidal strength capable of triggering cooler ocean-surface temperatures.

Weiss's sweeping conclusions, extrapolated from extremely limited data, have been challenged by archaeologists, one being Norman Yoffee, who prefer to emphasize the political and cultural factors that destabilized the Akkadian empire or who question, as Richard Zettler has done, the premises of Weiss's theory. Recent research by paleoclimatologists, however, focusing on sediment cores, ice cores, and lake pollen records from central and West Asia, Africa, and North and South America has tended to support the theory of a global shift to a much more arid climate a little over 4,000 years ago. Weiss and other archaeologists of both the Old and New World contend that the demonstrated scale of the climate change would have had a severe effect on even established polities of the time, such as the Akkadian empire.

Changing Waterways in Ancient Mesopotamia

At the height of the last Ice Age, global sea levels were some 100 meters lower than they are today. The whole Gulf was dry land, through which flowed the Tigris and Euphrates rivers. Global sea levels began to rise from around 14,000 BCE, rapidly drowning the shallow Gulf, which reached its present shores by 5000–4000 BCE. By 3000 BCE waters in the Gulf may have risen a further 1–2 meters, bringing the coast some 150 kilometers farther northwest and reaching nearly to Ur, which is recorded in early texts as a port.

When and how did the Gulf achieve its present shoreline? Alluvium deposited by the rivers may gradually have enlarged the delta, causing the head of the Gulf to retreat, although an important study by Lees and Falcon suggests that this alluviation was balanced by subsidence caused by continued tectonic activity. There is some evidence that the present shoreline had been reached by around 1500 BCE, but other data suggest that this did not happen until around 1000 CE. Since the region at the head of the Gulf is very flat, slight changes in the levels of sea and alluvium can cause significant changes in the line of the coast, and flooding can create new areas of swamp. It is therefore difficult to determine when and in what way the shape of the region developed over time. Deep-sea core evidence may indicate that before 4000 BCE extensive annual flooding made southern Mesopotamia mainly marshland and that during the later fourth millennium this region became drier, at first creating a land crisscrossed by waterways but by 3000–2800 BCE becoming similar to the way it is today.

As rising postglacial sea levels progressively flooded the Gulf, the changing location of the coast affected the gradient of the rivers, causing the upper reaches to become more deeply incised and therefore generally stable in their location, but slowing their flow across the plains so that an increased volume of alluvium was deposited there. Just north of Sippar, the plain broadens out and its gradient declines, causing the rivers to become far less stable. The Euphrates

in particular has split into a number of major and minor branches, and in years of heavy flooding these can change their course, with devastating effects for their dependent settlements. Before 3000 BCE, the Euphrates flowed in three channels, passing through Kutha, Kish, and Jemdet Nasr; by the third millennium, the Kish branch had become the principal one. Around the end of the Early Dynastic period I (ca. 2750 BCE), the main flow of the Euphrates farther south moved eastward to run down a previously minor branch, reducing water in its former main channel. Uruk, on the latter, though still a major city, declined from its earlier preeminence, while cities on the eastern branch, including Umma, grew in importance. During the later third millennium, a minor branch developed though Babylon, growing to become the principal branch by the late second millennium BCE. Today the principal bed of the Euphrates lies farther west.

The Euphrates is not alone in changing its course. Below Kut, the Tigris is also unstable and is known to have shifted at least three times. In antiquity, it flowed directly into the Gulf, having followed a much more direct course than that of today. The Diyala anciently joined the Tigris considerably south and east of their present confluence near Baghdad. And until around a millennium ago, the Karun and Karkheh in Susiana formed a joint estuary.

Evidence from pollen cores and oxygen isotope profiles from mountain lakes gives some indication of variations in vegetation, rainfall, and temperature, although many uncertainties remain. Temperatures exceeded those of today by 1–2 degrees Celsius around 5000–2000 BCE. This, combined with higher rainfall, allowed trees to grow at higher altitudes and in regions of steppe that today have sparse vegetation. A period of reduced rainfall in the northern mountains from 3800 BCE may have caused the marshes of southern Babylonia to become progressively drier. Further evidence suggests that the years around 2900 BCE saw particularly severe inundations. During the third millennium BCE, river levels may have fallen, particularly around 2350–2000 BCE, necessitating increasing investment in irrigation works. Later episodes of fluctuating river levels included peak volumes of water in both

SEALAND

The extreme southwest was until very recently a region of marshland; drained by order of Saddam Hussein, it is now being restored again to marshland. Around Qurnah the Tigris and Euphrates combine to form the Shatt al Arab, joined by the Karun from the east before discharging their waters into the Gulf. In antiquity, however, the rivers flowed independently into the Gulf. South of Nasiriyah on the Euphrates and Amara on the Tigris, the waters of the delta spread out to form a huge area of perennial marsh, lakes, and waterways. Reed beds and rushes cover the area, and date palms grow along the waterways. There is abundant wildlife—fish, shellfish, turtles, and waterfowl—and fowling, harvesting dates, and fishing have always offered a productive way of life in the area. In times of political unrest, the marshland has also served as a place of refuge for defeated soldiers, escaped slaves, and other fugitives.

—Jane R. McIntosh

the Tigris and the Euphrates around 1350–1250 BCE, followed by a reduction that lasted until around 950 BCE.

Ongoing research using remote sensing continues to reveal and clarify the complex history of the development of the Gulf coastline and the southern Mesopotamian alluvium and the changing courses of Mesopotamia's rivers.

The Formation of Agroecosystems in Europe

The formation of agroecosystems was the greatest single ecological change in Europe's preindustrial human history. Whether cultivating plants, harvesting edible parts of plants, slaughtering animals, storing food, or controlling propagation, agricultural activities modify the ecosystems upon which they rely. As in other ecosystems, green plants capture solar energy, which then flows through food webs to animal organisms, gradually dissipating into uselessness (entropy). Plant growth requires water and nutrients, whether provided by natural processes or human agency.

Agroecosystems, however, are highly simplified food chains and are inherently unstable. Humans typically manage agroecosystems to favor a few annual plant species (cereal grasses in the case of Europe), subsidizing their growth with nutrients and water to gain high productivity (though less than the total productivity of the diverse species in a natural ecosystem). These plants concentrate their entire growth and reproductive cycle into high-speed circulation of nutrients during a single growing season. Because in nature such pioneer organisms soon give way to other, longer-lived ones, agricultural work is required to keep the system at this simple stage. These systems are unstable, as they require subsidies and export the favored consumable biomass to humans elsewhere.

More broadly, farmers alter vegetation by clearing forest and controlling weeds; they alter the composition of topsoil by hoeing or plowing; they drain and divert water; they retain seeds for

further planting; and by selecting for desirable characteristics, they often render certain plants unable to reproduce on their own. Such changes may be significant at the microlevel, but for the early and middle Neolithic of northern Europe we must apply a wider lens.

Neolithic farmers did not fully re-create the mosaic landscape bequeathed to them by the Mesolithic (i.e., deciduous forest containing open areas), though they did clear more and larger openings in the forest with polished stone axes and by ring-barking and burning, leaving larger stumps to rot. The composition of the ancient wildwood remained intact. Far from being an unmitigated enemy, the forest provided pasturage for pigs and cattle, the latter grazing on edge grasses and munching on twigs, leaves, and young saplings. Ancient Britons practiced coppicing, allowing the cut stump of a deciduous tree to send up shoots used for cattle food, poles, and other purposes. The forest became more open, with increasing edge, clearings, and flourishing understory. One can imagine the small fields ensconced in woods that little by little developed into an agrarian landscape. Deer populations may have taken off as forest edge increased, hunting declined, and farmers began to kill wolves and other predators of both deer and livestock. Neolithic populations remained too small to take much of a toll on either forest or soil. No evidence of decreasing soil fertility comes from central Europe, though the earliest farmers in the region relied too heavily on cattle, an imbalance corrected in later prehistory by a partial shift from cattle to domesticated pigs. In this light it is best to see the Neolithic as the first stab at a long work-in-progress.

Environmental change accelerated in succeeding centuries. From the creation of landforms, such as some of the lowland heaths of Britain, to the podzolization of soil in Denmark, human communities began to rework ecosystems as agriculture expanded.

Climate Change at the End of the Late Bronze Age—Volcanic Eruptions in Iceland and Other Indicators of Climate Change

The end of the Late Bronze Age in the eastern Mediterranean and Near East (around 1200 BCE) coincides with a number of climatic changes evident from Europe to China. How significant these climate changes were to the collapse of Late Bronze Age civilization is heavily contested by scholars; there is no clear causal relationship between these instances of climate change and the transformations that Mediterranean society underwent at this time. That climate change occurred at this time, however, is clear from the environmental record identified by archaeologists and geographers.

The clearest evidence for Late Bronze Age climate change involves the eruption of Hekla, an extremely active volcano located in Iceland (Hekla III). Ice cores taken from Greenland and other evidence indicates that the eruption took place around 1135 BCE, give or take 130 years on either end. In Ireland, starting in 1159 BCE, tree ring growth is stunted for about two decades, which is the expected result if there had been a substantial eruption nearby. Significant amounts of volcanic soot that remain present in the atmosphere after an eruption will limit the amount of sunlight that reaches earth and thus stunt plant growth. However, recent climatological research suggests that these particulates all precipitate out of the atmosphere after two years,

➤ MISTAKING VOLCANIC ERUPTIONS FOR ECLIPSES

After a large volcanic eruption, soot and dust are spewed into the atmosphere. Called dust veils, these events can result in a variety of environmental problems, since the dust blocks the sun's rays. Depending on the density of the dust veil and global wind patterns, these veils can cause havoc significant distances from the eruption site. These dense dust veils can also create unusual visual anomalies, especially relating to solar observations. The sun may appear to have a pink corona around it, the color of the sun may appear to be different, or the sun may seem to have dimmed in intensity. Ancient astronomical observations lack the technical language that could differentiate this type of event from an eclipse. Thus, ancient records of eclipses may actually be records of dust veils.

—Kevin M. McGeough

which lessens the length of climate change. Historical records from Egypt indicate that there were crop failures around 1150, also consistent with this reconstruction. Records from the Shang dynasty in China refer to dust and ash rains around this time, which also may correspond to this eruption. That Hekla III erupted is well agreed upon by scholars, but the extent of the eruption's environmental impact is unclear. Not only is it unclear how significant this event would have been on ancient vegetation (and thus on subsistence practices like farming), it is also unclear how far away the effects would have been felt.

Another climatological debate related to the end of the Late Bronze Age (and possibly involving the Hekla eruption) involves reconstruction of precipitation variation from 1200 to 900 BCE. Evidence from tree rings points to very heavy precipitation in some parts of Turkey at this time, but in Mesopotamia, Syria, and possibly the Greek world, there may have been a significant reduction in precipitation. These unusual precipitation patterns may have had a very severe effect on the precipitation agricultural economies of these regions.

■ Introduction: Crops and Animal Products

During the period from 4000 to 1000 BCE, world populations became more and more reliant on domesticated crops. The process of domesticating plants began prior to this period, yet it continued on and still continues today. By 1000 BCE, much of the world's people were dependent on agricultural produce, with North Americans and Australians being notable exceptions.

Archaeologists can recover evidence for ancient crops in a number of ways. Ancient textual accounts from Mesopotamia and Egypt record crop types, crop yields, and instructions for proper planting techniques. Sometimes the crops themselves survive directly as seeds and/or carbonized remains or indirectly as impressions on clay pots. Residues from plants are sometimes left on tools. In the Near East, stone sickles with a shiny sheen on the blade are often recovered. This sheen is from the plant silica that accumulates on a stone tool when it is used to cut down plants. Iodine can be used on ancient tools to determine if the tool was used to cut down starchy plants, since iodine changes color when exposed to starch. Biologists can also study modern plant samples, attempting to reconstruct the genetic history of plants in a given region.

The study of ancient pollen provides a broader understanding of changing vegetation patterns in a given region. Pollen itself is virtually indestructible, so if treated carefully, it can

be recovered at many sites. The results of a palynological analysis provide an idea of fluctuating ratios of different types of vegetation over time. By comparing different pollen levels, it is possible to reconstruct the history of the region's plant life. For example, an early level may present evidence for oak, elm, and pine trees as the dominant types of plant life, which is indicative of a forest. Following this, the amount of these trees drop dramatically (a larger drop than could be explained through natural processes) and is replaced by wild grasses and weeds, which is indicative of forest clearance. Following this, the pollen of various crops (and associated weeds) makes up a significant proportion of the overall numbers of plants, suggesting that what was once a forest had become farmland. After this, a drop in the amount of crop pollen and the return of oak or pine pollen would indicate that the farmland had been abandoned and that forest had been allowed to return again.

—Kevin M. McGeough

Wheat and Barley

Wheat (of which several varieties were grown) and barley (*Hordeum vulgare*) are the key domesticated plant crops of the ancient Near East. Without the steady surplus food supply created by these crops, the urban civilizations that developed in Egypt, the Levant, Anatolia, and Meso-

➤ BARLEY—TO EAT OR TO DRINK?

Barley was one of the first domesticated crops. Barley could be used to create gruel and coarse flour for bread. Naturally occurring yeast in the air mixing with such gruel may have been responsible for the discovery of the rising action of yeast needed to make leavened breads. In addition to leavening, such naturally occurring yeasts can cause further fermentation. Yeast fermenting the natural sugars in accidentally sprouted barley (barley malt) and water may have resulted in the world's first beer. The resulting barley beer would become the common beverage of the inhabitants of both Sumer and Egypt sometime after the fourth millennium BCE.

Beer is high in calories and resistant to bacteria due to its alcohol content. This would help reduce the risks of contracting many common infections carried in water contaminated by human or animal waste. More importantly, stored grain or flour is at risk from pests. Typically, 25 percent of the yield of barley was lost each year to various pests such as mice, rats, and insects. Beer, however, is not attractive to these pests and is more easily stored in clay jars than grain, which needed to be stored in vast pits or granaries. In addition, beer had the advantage of adding welcome variety to the diet and also had the bonus of being an intoxicant. This made the appeal of brewing very high, since in many ways it was the most efficient means of getting the most caloric yield out of the sown barley seeds.

This early beer would have been very different from modern beers. Hops, which produce much of

the flavor in modern beers, were not added. The beer in Mesopotamia was made using baked cakes of barley flour mixed with barley malt (dried sprouted barley) and date honey. The brewing liquid was not as well processed as today, and it was common for the beer to be full of chaff and pieces of sprouted grain. As a result, the earliest images of beer drinking found in Mesopotamia show it being drunk from large pots through straws with filters on the end. Typical pottery vessel shapes in this period throughout the Near East are vessels with spouts that are often called teapots. It is more likely that these vessels were used for beer and were meant to strain off the unpleasant solid bits and leave just the tasty liquid.

The question that remains is whether barley was first domesticated for food or for making beer. In 1953, a symposium was held among some of the leading scholars of the day to answer this question. Unfortunately, evidence exists for both arguments. The earliest barley was grown alongside early wheat, which may have been the main source of solid carbohydrates. This suggests that in those areas where barley was not a necessary crop, barley may have been grown primarily for beer from the outset. However, there is little evidence for the earliest beer manufacture, and what little early barley has survived is carbonized. Since deliberate burning of the barley would not be part of the process, this may suggest that it was used for other purposes.

—David R. Lipovitch

potamia would never have reached a population size sufficient to require or spark the creation of cities. Even had the populations been large enough to coalesce into urban centers, it was only through the extreme surpluses that were created by wheat farming in Egypt and barley farming in Mesopotamia that the immense public works projects typical of these cultures during their formative stages could be built and maintained.

Both barley and wheat were first domesticated in the hill country around Mesopotamia around 9000 BCE. These crops spread through-

out the Near East and were being cultivated in Egypt by about 5000 BCE. In Mesopotamia, barley was the crop of choice due to its resistance to salt. The nature of farming in the Mesopotamia plane, which required irrigation, resulted in soils quickly becoming saline. Wheat would not have been able to tolerate such soil conditions, but the otherwise rich soil deposited as alluvium by the Tigris and Euphrates rivers yielded huge harvests of barley that rival modern yields. The barley could be parched, cooked as gruel, made into flour and baked into bread or cakes, or, most importantly in Mesopotamia, used to make

beer. While barley was less important as a crop in Egypt and the Levant, it was also grown there primarily to make beer, which was the main beverage of the average person. Beer was an ideal way, in a world without pesticides, to get as many calories from the grain as possible without losing your yield to insects and other vermin.

In Egypt the situation was quite different. Thanks to the regular flooding of the Nile, the occupied parts of Egypt were well watered and covered with an extremely rich layer of silt. The force of the annual inundation drove out any salt in the soil and prevented the buildup of any salinity. The inundation also came at the right time of year to be of the most benefit to wheat growing. The main crop in Egypt before the Ptolemaic era, when durum wheat was introduced, was emmer (*Triticum dicoccum*). The yields for wheat under these conditions were incredible and guaranteed a surplus every year that could be stored for use by the central government in times of famine or to provide food for the vast temple establishment and other state employees. In addition to the wheat grown for bread, the Egyptians also grew barley, which was used to make beer.

The growing schedule of this wheat and the nature of the Nile meant that during the summer months, farmers had few tasks to deal with (unlike Mesopotamia, where constant irrigation and tending of the fields, canals, levees, and drainage ditches was necessary). This left them available for the construction of immense government-sponsored building projects such as the pyramids typical of the Old Kingdom in Egypt. Thanks to the huge surpluses created, the state could pay the workers in the form of rations of bread and beer. Without the food surpluses created by the growing of wheat and barley in Egypt and Mesopotamia, the complex societies of Sumer and Old Kingdom Egypt would never have come to be realized.

The Spread of Rice

Asiatic rice is indigenous to much of South and East Asia. Recent genetic studies have demonstrated that it separated more than 200,000 years ago into two forms, the annual *Oryza nivara* and the perennial *O. rufipogon*, which were domesticated in two separate areas, giving rise respectively to the long-grained *indica* in India and the short-grained *O.s. japonica* in China. This has prompted a reexamination of the supposed *indica* and *japonica* grains from early Chinese sites. It now appears that wild rice was brought under cultivation by 6000–5000 BCE in the middle and lower Yangzi Valley, where by around 4500 BCE it had evolved into domestic japonica.

Contact between rice farmers in the Yangzi Valley and millet farmers in the Yellow River basin encouraged the spread of rice to northern China, where it is known by 3000–2500 BCE and appears in quantity in Longshan sites (2500–2000 BCE). It is likely that plows (evidenced by stone plow tips) were used for ground preparation in both North and South China, but there is

no clear evidence before the later second millennium BCE of the domestic water buffalo needed to draw them.

Rice cultivation may have been introduced to Korea over land through northern China or by sea directly from the Yangzi region. Although the earliest finds of imported rice in Korea date to around or before 2000 BCE, wet-rice cultivation did not begin here until later. Recently, paddy fields have been unearthed at Geumcheon-ni, Yaeum-dong, and Okhyeon dated to the late second or early first millennium BCE and to Ma-jeon-ni from the second quarter of the first millennium BCE. These include both lowland fields and small terraced hillside fields; some were associated with canals and reservoirs.

Rice was by now under cultivation over most of China. The earliest Neolithic site in southern China is Shixia, dated to around 2800 BCE. The farming communities on Taiwan were cultivating rice by around 2500 BCE at, for example, Nu-anguanli; the appearance of rice husks in pottery coincides with the common use of stone harvesting knives. The associated remains of foxtail millet suggest that the rice was introduced from the Shandong Peninsula, where both crops were cultivated by the early third millennium, rather than directly from the Yangzi Valley. Cultivated rice spread to the Philippines by 1500 BCE and was found at, for example, Andarayan in Luzon.

Wild rice was one of many plant foods exploited from early times in Southeast Asia; it is known from around 3000–2500 BCE at Banyan Valley Cave. Nevertheless, it now seems likely that rice cultivation and agriculture in general were introduced to Southeast Asia rather than developing locally. From around 2300 BCE, a few villages are known in parts of mainland Southeast Asia—such as Non Nok Tha, Ban Chiang, and Ban Non Wat in Thailand—whose inhabitants combined hunting, fishing, and probably gathering with agriculture, raising domestic pigs, dogs, and cattle and growing rice. By 1500 BCE there were communities right across mainland Southeast Asia that were also working bronze and among which rice cultivation was by now an important subsistence practice.

Geneticists favor the Indian foothills of the Himalayas as the region where indica rice was

➤ RABI AND KHARIF CULTIVATION

Although the Harappans were experienced and innovative farmers, there were constraints on cultivating rice that probably account for its relatively late adoption. Harappan agriculture was based on a range of crops, including wheat, barley, and pulses that required winter temperatures and were sown in November or December and harvested in April or May. This is known locally as *rabi* cultivation. In contrast, the local flora required summer temperatures to grow and the shortening days of autumn to reach maturity, taking advantage of the moisture offered by the summer floods and monsoon rainfall, the latter being particularly relevant in Gujarat. These plants, including rice and some millets, pulses, and vegetables, were probably first incorporated into the diet as gathered wild plants. Bringing these under cultivation required planting around June or July for harvest in October (*kharif* cultivation), a major change in the pattern of agriculture.

A shift from *rabi* cultivation alone to *rabi* supplemented by some *kharif* cultivation occurred at Harappa in period 3C (ca. 2200–1900 BCE). By the Late Harappan period the mosaic of differing local crop mixes and *rabi*-*kharif* balances was well developed in some previously settled Harappan regions such as Gujarat, while in others such as the Kachi plain and in new areas such as the Deccan and the Ganges-Yamuna doab it was still evolving.

The addition of *kharif* crops brought a number of advantages. The ability to plant a summer crop if spring harvests were poor offered an important assurance against food shortages in the Indus region, where yields could be high but where there were ever-present dangers of crop failure due to drought, excessive flooding, or changes in the course of the rivers. Rice could be grown in areas too wet for other cereals to thrive. New crops increased the diversity available in the diet. Finally, *kharif* crops enabled double-cropping to be practiced, allowing two crops to be obtained from the land during a single year.

—Jane R. McIntosh

domesticated, although both genetic and archaeological evidence show that this may have occurred in several separate locations. Rice was among the wild plants exploited by hunter-gatherers in the middle Ganges region from early times. Claims that domesticated rice was present in middle Ganges sites from the fifth or even seventh millennium BCE are unsupported, but from the third millennium rice (and other local cereals) was certainly under cultivation here in several areas, including oxbow lakes in the central Ganges Valley, the valleys of the Son and Belan rivers, and the Vindhya hills at sites such as Damdama, Senuwar, and Mahagara, often alongside continued hunting and gathering. Farther to the south and east, at Golbai Sassan, Gopalpur, and other sites in Orissa, rice cultivation probably began a little later, around 2000 BCE, and was certainly established by 1500 BCE; this was quite possibly a separate center of rice domestication.

Rice grew wild in Gujarat. Charred rice husks and impressions of rice husks and leaves were found here in Indus (Harappan) pottery (ca. 2600–1900 BCE) at Lothal and Rangpur. Rather than indicating rice cultivation, this probably reflects the use as a pottery temper of dung from cattle that had grazed on wild rice. However, other third-millennium rice grains or impressions are known outside the area in which wild rice grew, at the Indus city of Harappa, at Ghali-gai and Birkot Ghundai in Swat, and at Early Harappan Balu and Kunal in the eastern Harappan region. By the early second millennium, rice was certainly being grown in the latter region, such as at the Late Harappan site of Hulas.

While it is possible that the Harappans domesticated rice themselves, there is an alternative. By 2500 BCE some sites of the middle Ganges region had wheat, barley, and sheep introduced from the northwest, presumably due to indirect contacts between the middle Ganges groups and the Harappans. It is not unreasonable to suggest that this may have been a two-way traffic, with domestic rice being introduced to the Harappans by the same means. This may be supported by linguistic evidence: Language X, known only from a few words, seems to have been the language spoken in the Ganges Valley, while Paramunda is an Austro-Asiatic language that, it has

been argued, was spoken in at least the Punjab in Harappan times. The word for rice in Paramunda seems to have been adopted from Language X, presumably as the label accompanying the introduced crop.

An increasing population in the Kachi Plain was associated in the early second millennium with combined winter cultivation of cereals and pulses and summer cultivation of rice and millet. Surprisingly, this was apparently japonica rather than the indica rice that was cultivated at this time in neighboring Punjab and by Late Harappan communities farther east. This may perhaps be explained by the increased internationalism of this period, when Baluchistan and the Kachi Plain had strong links with the region to the north, stretching to Afghanistan and beyond. While organized long-distance connections between China, central, and South Asia did not develop until the first millennium BCE, there was a trickle of goods, plants, animals, and ideas passing from east to west and west to east much earlier. In the later third or early second millennium BCE, some artifacts and practices (such as dog burial) in Kashmir strongly resembled those of China, and wheat and barley reached China from the west, demonstrating the existence of indirect links between South Asia and China.

Summer rainfall, coupled with water in seasonal streams and rivers, made it possible to grow rice in the Kachi Plain, where it was the main crop at Pirak from around 1700 BCE. Elsewhere in the Indus basin, rice could be cultivated by sowing it in dhands (seasonal lakes) created by floodwater retained in depressions. The margins of Lake Manchar would have provided ideal conditions, as they do today. However, in the Ganges-Yamuna doab and areas to the east, summer monsoon rainfall was adequate to provide water for growing rice, and this is reflected in the cultivation of rice in Late Harappan sites in this region, the gradual southeastward extension of the land under cultivation during the second millennium, and the spread of farming communities into the Ganges Valley in the first millennium.

Rice cultivation also developed in western India during the second millennium. Rice was one of the crops grown both by the Late Harap-

pan inhabitants of Gujarat and by the Ahar-Banas people in Rajasthan with whom they had links. However, rice cultivation apparently did not spread into South India until the first millennium BCE.

Olive Oil

Olive oil was a highly prized commodity in the ancient world. Olive oil was used as a cooking medium, a condiment, a lubricant, fuel for lamps, a base for perfumes and unguents, and soap. The olive (*Olea europaea*), however, only grows in very specific environments and requires a great investment in time and energy before the trees will yield fruit. As such, in those areas where it was grown (such as the Levant) it became a key trade commodity.

The earliest evidence for the domestication of olives comes from the Chalcolithic (ca. 4300–3300 BCE) site of Teleilat Ghassul in present-day Jordan, where olive stones were found alongside vats used for crushing the olives. The site is in close proximity to sources of wild olives. There is evidence in the Levant that during the Early Bronze Age II and III (3050–2300 BCE), a new form of pottery called Metallic Combed Ware appeared. It is often thought that this new style of pottery, which included separator vats and large storage jars, is evidence of the first olive oil industry (rather than home production), supplying oil both locally and for export abroad.

➤ HOW OLIVE OIL WAS MADE

A reconstructed olive press in the courtyard of a dwelling at the archaeological site of Hazor in present-day Israel. Olives were first crushed in a basalt basin, then placed in a press, where the oil was extracted with the help of weights hanging from a long wooden lever. (Pictorial Library of Bible Lands)

Ripened olives are harvested by handpicking or by shaking or beating the tree with a long pole. The harvested olives are then crushed in presses to release their oil. The initial pressing, which releases the oil without mixing in any of the bitter pulp, is considered the best method and is referred to today as cold-pressed extra virgin. In order to get the largest possible yield, the remaining olive pulp could be pressed multiple times and doused with hot water to release even more oil. As the pressings continue, the oil becomes less and less palatable but remains useful for fuel.

—David R. Lipovitch

Raw olives are unpalatable and must be pickled to make them edible. It is generally thought that the pickling of olives did not occur until late in the first millennium BCE. There is, however, some evidence (in the form of olive stones found in single-use cooking fires at the Middle Bronze Age site of Ashkelon in Israel) that they may have been eaten as early as the first half of the second millennium BCE. It is clear, therefore, that olives were initially cultivated as a source of oil.

Olives were grown along much of the coast of the Mediterranean Sea. They require an average temperature of 15 degrees Celsius to grow but also need a period of cold weather for the

fruit to ripen. This meant that olives could not grow in Egypt or Mesopotamia where the winter weather does not get sufficiently cold. Olives require a great investment of time before they yield fruit. They generally do not even flower until they are five to six years old. This is why there is an injunction in the Hebrew Bible (Deut. 20:19–21) on the destruction, even during wartime, of olive trees and other fruit trees since replacing them would take so long. As a result of their limited habitat and the investment needed in raising olives, olive oil became an important trade commodity for those ancient cultures living along the Mediterranean coast where this fruit could be grown. This may be one of the key reasons that Egypt always took a keen interest in the Levant. Since their attention often sparked local cultural developments, it can be claimed that olive oil was a key element in the development of complex societies in the Levant.

Previously, linseed oil produced from the flax plant was used as the main source of oil in the ancient Near East, but it is largely unpalatable. While it made a decent fuel, its use in cooking would have been minimal. The pleasant taste and aroma of olive oil would have made it an excellent replacement for linseed oil and therefore a highly valued commodity.

Dates

Dates are the fruit produced by the date palm (*Phoenix dactylifera*). They are native to the oases of North Africa and of southwestern Asia. As a result, they were available to the earliest cultures of Egypt, the Levant, Mesopotamia, and the Indus Valley, whose inhabitants relied on dates as an important dietary supplement and as a source of raw materials. Date palms are fairly

salt-tolerant (making them ideal for Mesopotamia, where the soil was often saline), prefer warm climates, and are resistant to drought (and thus ideal for planting in oases to feed caravans). A typical tree can yield between 8 to 10 kilograms of dates, but an older tree, even without modern cultivation techniques, can yield up to 80 kilograms of fruit per harvest.

Wild date stones were found at the Paleolithic site at Shanidar Cave in Iraq dating to about 50,000 years ago, when they were already being collected for food. Domesticated date stones have been found preserved at several Chalcolithic sites (ca. 4300–3300 BCE) in the Levant including the Cave of the Treasure (Nahal Mishmar) in Israel and Teleilat Ghassul in Jordan. It is generally assumed that dates were being cultivated as early as 4000 BCE throughout the region from northeastern Africa through the Persian Gulf.

Dates are remarkably high in calories (dried ripe dates have about 29 calories per date, about two-thirds of the calories of an equivalent amount of pure sugar) and are rich in protein, calcium, potassium, dietary fiber, and B-complex vitamins. As such, they played an important role in the diet of the people of the ancient Near East. The fruit could be eaten fresh or dried and at various stages of ripeness. Harvested dates could be molded into dried cakes for long-term storage. Dates could also be further processed to make date honey, which in the absence of sugar would likely have been the main sweetening agent. By letting the date honey ferment, it could also be made into a potent alcoholic beverage known as palm wine.

In addition to the fruit itself, the wood was used as timber (although of poor quality) and could be used for construction or as fuel. The leaves could be used as roofing material or for basketry, and the seeds could be used as animal fodder. As a secondary ingredient, date honey played a major part in flavoring breads and in producing beer. As such it would have played a huge role in the ancient diet, particularly that of the ancient Sumerians among whom much of the caloric intake may have come from dates either directly as food or indirectly as part of their beer. Dates, which grew primarily in the southern part of Mesopotamia, were an impor-

tant early trade good and were often traded into northern Mesopotamia in return for local commodities. Until recently, Iraq led the world in date production.

Maize

Maize (*Zea mays*, corn) is the key crop grown by most New World cultures. Without maize agriculture, population size was limited by the number of people who could be supported through hunting and gathering. The development of maize-based agriculture alongside beans and squashes allowed populations to swell and become more sedentary, and with this change came the possibility of urbanized cultures. Without

THE MYTHOLOGICAL ORIGINS OF MAIZE

Maize (corn) was the key crop grown by the early North American and Mesoamerican civilizations. It was only through the surplus created by these crops that complex urban societies such as the Olmec, Maya, Aztec, and Toltec were able to develop in the New World. As a result of its incredible importance in day-to-day life, maize was also to play a key role in the mythology of these cultures. The myths associated with the discovery of corn may help enlighten archaeologists and historians about the events involved in its actual domestication.

The most common Mesoamerican myth of maize origins involves a fox who follows an ant and discovers a stash of maize enclosed within a large mountain or boulder, eats the grain, and decides that he has found a wondrous new food. In most versions the maize remains trapped within the mountain or boulder and is only made accessible to humans by a deity blasting open the mountain with a thunderbolt. This explains why maize kernels occur in a range of colors depending on how close they were to where the lightning struck.

Among the Maya of Guatemala there was a belief that in antiquity there was no maize and that humans ate the roots of a plant called *txetxina*, meaning “mother maize.” This plant had a large

root and a single stalk much like the postulated wild predecessor of domesticated maize. These stories tell how maize was discovered when people spotted it in the dung of a wildcat.

Maya creation myths tell of three gradual improvements of creation. Humans were created from mud, then out of wood, and finally from maize dough, with the dough proving to be the ideal human flesh. Similarly among the later Aztec there was a progressive improvement upon creation. This idea is further developed in the much later creation myths of the Aztecs of central Mexico, which tell of the present world having been created after a succession of four previous eras, or suns. The food that humans consumed improved during each subsequent phase of creation. In the First Sun, gathered acorns and fruits were the primary food. In the Second Sun, humans progressed to pine nuts. In the Third Sun, it was millet. In the Fourth Sun, it was *teocentli*, meaning “great or divine grain.” This would appear to refer to the immediate ancestor of maize. Finally, during the Fifth Sun, the food provided by the gods was *centli*, modern cultivated maize. This myth suggests that the Maya had a recollection of an era when they gathered the wild progenitor of maize before it was domesticated.

—David R. Lipovitch

maize the various cultures that existed with the arrival of Europeans in the New World would never have reached their level of complexity.

Unlike the domesticated plants of the Old World where the process of domestication is now fairly well understood, in the New World archaeologists are still trying to uncover the history of maize domestication. Since all evidence of preserved corn found to date in the New World are of already domesticated maize, it is unclear what the original wild forebear of corn was. The earliest preserved corn found to date was discovered in the 1960s by Richard “Scotty” MacNeish at Coxcatlan Cave in Tehuacán, Mexico. The oldest of the recovered corn cobs was radiocarbon dated to 5050 BCE. While quite primitive in shape and form (not like modern corn), they were definitively maize and not some wild species of grass or a primitive hybrid of two wild species.

There are a number of different hypotheses currently in vogue that may explain the development of domesticated maize. The Wild Maize Hypothesis claims that there must have once been a wild form of maize, now extinct, from which the cultivated form evolved. The problem with this theory is that no preserved remains of such wild maize have ever been found. The Orthodox Teosinte Theory says that maize was derived from the wild grass teosinte (*Zea mays mexicana*). Variants of this theory include the possibility that maize is a hybrid of teosinte and the as-yet undiscovered wild maize or of teosinte and another related wild grass. Finally, the Catastrophic Sexual Transmutation Theory holds that through a series of genetic mutations the teosinte tassel spike (the male reproductive organ) was transformed into the maize ear (the female organ) as opposed to more conventional approaches that have the maize ear developing from the teosinte ear. The idea that maize develops quickly as a result of a mutation may explain the lack of wild maize in the archaeological record. Recent DNA and related studies do indicate that teosinte is extremely closely related to maize and likely descended from it, but exactly how is still unknown.

In whichever way maize domestication occurred, by 2700 BCE this new crop had spread from Michoacán to Puebla in Mexico. By 1400

BCE maize cultivation had reached both Mexican coasts and was spreading to other parts of Mesoamerica. By 500 BCE it had reached into much of the United States (first appearing at Bat Cave around 1000 BCE) and had reached as far north as Ontario, Canada, by about 1000 CE, becoming the staple crop in much of the New World.

Chili Peppers

Despite the fact that chili peppers are associated with cultures worldwide today, they are a New World crop that was only introduced to the rest of the world after 1492 and the European discovery of the New World by Columbus. Chili peppers (*Capsicum* sp.) are a member of a large family of plants, related to the nightshades, that includes at least 25 species. Due to some taxonomic uncertainty, there is some debate as to whether 4 or 5 species were actually domesticated. The 5 species generally cited as domesticated are *Capsicum pubescens* (South American rocoto peppers), *Capsicum baccatum* (chiltepin), *Capsicum annuum* (bell peppers, jalapeños, and paprika), *Capsicum chinense* (habaneros and Scotch bonnet peppers, the hottest of the peppers), and *Capsicum frutescens* (cayenne and tabasco peppers). *Capsicum annuum* is the best known of the domesticated species and was the first introduced into the Old World by Columbus. *Capsicum chinense* was also discovered by Europeans at an early date, but while it spread globally it did so to a lesser extent than *C. annuum* probably because of its slightly later discovery in South America.

Due to numerous questions of biological taxonomy, much of the question of how and when chilies were first domesticated is still unclear. The pungent varieties of the chili pepper occur naturally in an area ranging from southern Brazil to Bolivia. Nonpungent related peppers occur in a larger area that includes Central America and

southern Mexico. Currently, it is thought that ultimately the chili pepper and its relatives originated in Bolivia but that the various types of peppers were domesticated more locally and independently. For instance, *C. annuum* appears to have been first domesticated in Mexico, while the other species appear to have South American origins. Thus, there were multiple centers of chili domestication. It is also unclear what the forebearer of chili peppers was. Wild *C. eximium* and *ulupica* (*C. cardenasii*) have been suggested as possibilities. Both of these species are native to Bolivia. Domestication of the species resulted in chilies becoming deciduous plants with much larger fruit than the wild varieties. The natural means of seed dispersal, through ingestion by birds, was also lost as a result of domestication.

Evidence for the first use of the various types of chili peppers is spread across the New World. The earliest evidence for the use of chili peppers in the archaeological record comes from the Tehuacán Valley from between 7000 and 5700 BCE. It is unclear whether these remains represent a wild form of *C. annuum* or an early domesticated form. Definitively cultivated chilies were recovered from the same area dating to around 1170 BCE. The earliest clearly domesticated chili peppers, however, come from Huaca Prieta in the South Andes of Bolivia and date to 3300 BCE. The remaining domesticated forms of capsicum were probably domesticated around 400 BCE.

Millet and Sorghum

Millet is a general term for small seeded cereal plants that grow around the world. The term is not taxonomic; it reflects the fact that these crops share a number of similarities, both in morphol-

➤ SESAME

Sesame is a flowering plant native to the Indian subcontinent that has subsequently spread to Africa, the Near East, and tropical regions around the world. The plant is cultivated for its seeds, which are rich in protein and oil. Sesame oil was used extensively in the ancient Near East because it is very flavorful and does not go bad easily, even in high heat. Sesame is suitable for small-scale cultivation; the seeds scatter very easily, so harvesters must be quite careful with them. The plant itself is quite resistant to all sorts of bad conditions, including drought, pests, and hot temperatures. Sesame plants are usually not irrigated but are fed through rain. Thus, in the ancient Near East, the crop would not have been grown above the isohyet.

Sesame seeds have been found at Harappa, in Pakistan. These are the oldest seeds that archaeologists have yet recovered. This is consistent with the biological evidence that suggests that the sesame plant was native to South Asia. However, most evidence for sesame oil usage comes from Mesopotamian textual accounts. Sesame is mentioned in many economic texts as a commodity that was traded. The word "sesame" in fact has Semitic roots, and likely the etymology can be traced back to the Akkadian language (in Akkadian it is called *shamashshammu*). Sesame seeds may also have been present in King Tutankhamun's tomb in Egypt. This evidence is enough to demonstrate the wide usage of sesame oil in the ancient Near East.

—Kevin M. McGeough

ogy (form and shape) and behavior. In general, they are grasses that can grow in very inhospitable conditions yet still provide significant food yields. People eat the seeds of millet, which are encased in hard, indigestible hulls. These hulls must be removed before millet can be consumed. Out of the hulls, the seeds look like little yellow spheres with a hole in one side (where it was attached to the stem). The nutritional value of millet is similar to wheat. Millets were cultivated very early in East Asia; different types of millets began to be cultivated in Africa, India, and Eurasia in 4000–1000 BCE.

» CACAO

Cacao and chocolate are made out of the seeds of the Cacao tree, a tropical evergreen tree probably native to the Amazon region of South America. The seeds (more often referred to as beans) are found in pods that vary from 6 to 12 inches (15 to 30 centimeters) in length. The seeds number 20 to 60 in a given pod and contain a significant amount of fat (known as cacao butter). The name is derived from the ancient Nahuatl language, and its scientific name (*Theobroma cacao*) literally means “food of the gods.” The Olmecs of Mesoamerica cultivated cacao; most scholars believe that the tree was exploited long before this.

Cacao trees are very fragile and require considerable care and maintenance. In ancient times the tree had to be kept well shaded, which was not difficult under the thick forest canopy of the Amazon. The tree needs very good soil and consistent rainfall. The trees could not be climbed, so to harvest the pods, long cutting implements had to be used. The yields of trees are very low, especially given the amount of work that is required in cultivation. No doubt the difficulties in growing, harvesting, and transporting these trees lay behind the value that cacao held in ancient times. Modern agricultural techniques have reduced the difficulties (and thus the costs) of cacao cultivation.

—Kevin M. McGeough

Millet is well suited for the African climate. Many varieties need very little rainfall, growing quite well in arid and semiarid environments. As with any successful desert grass, many varieties of millet are able to establish themselves within a short growing season. This makes it particularly difficult to identify where the first cultivation of millets may have taken place in Africa since it could have been anywhere along the southern margins of the Sahara Desert. Archaeologists have found evidence for pearl millet along the Saharan fringes and in northern Ghana dating to about 1000 BCE. Finger millet has been identified at the site of Kadera in the Sudan dating to about 3000 BCE, making it the earliest known millet crop in Africa. At Kadera, ceramic potsherds were discovered that had plant im-

pressions on them, allowing archaeologists to be certain that the ancient human inhabitants of Kadera had access to millet.

Sorghum was also found impressed onto potsherds at Kadera. The term “sorghum,” like millet, actually refers to a wide variety of species of grasses. Sorghum—which is native to Africa—has characteristics similar to weeds that allow it to spread quite rapidly. There are two general theories about where in Africa it first came into use as a domesticated crop. Ethiopians may have learned agriculture from the ancient Egyptians at some point during 4000–1000 BCE and applied this knowledge to the cultivation of sorghum, or sorghum may have gradually become domesticated during 4000–1000 BCE anywhere on the savannahs of Africa (from Sudan to Nigeria). It was probably cultivated in this region by 3000 BCE.

Sama millet was first domesticated on the Indian subcontinent around 2500 BCE. Archaeologists found carbonized grains at the Harappan site of Rodji (in India), Harappa itself (in Pakistan), and numerous other sites, indicating widespread human exploitation of this crop at the time. This is not surprising since sama is drought tolerant and does not require good soil to grow in, thus making it an ideal crop for the environment of the subcontinent. Many other types of millets (probably introduced from Africa) have been found in South Asian contexts, and it is likely that millet played an important role in Harappan subsistence practices.

Throughout the European Bronze Age, proso millet spread throughout the continent, especially in southern Europe. Although still grown in some parts of Europe, it is no longer used for human consumption. This crop likely originated in China, where it is attested archaeologically at least 5,000 years ago. It is still used in China today, an important component of some types of bread.

Palm Oil

Palm oil is a vegetable oil produced from the fruit of the oil palm tree. The oil was used for cooking in ancient times; it could also have functioned as a lubricant, but there is no positive evidence for this use in the period 4000–1000 BCE. It may also have been included in soups, sauces, and dough in ancient times, as modern ethnographic analogy would suggest. Several kilograms of palm oil were recovered from Early Dynastic period tombs at the site of Abydos in Egypt, proving that palm oil has been used in Africa for at least 5,000 years and probably longer. The Egyptians may have produced this themselves or acquired it from other parts of Africa. Archaeologists have found remnants of oil palm trees dating from 4000 to 1000 BCE in West Africa, but this would not have been the only region that the oil palm grew in at this time.

The oil palm tree is native to West Africa and grows well in humid tropical regions. The fruit

➤ PALM OIL AS BIODIESEL—ENVIRONMENTAL SOLUTION OR PROBLEM?

The ancient oil palm tree has long been exploited because of its highly productive yields. In recent years, the governments of Thailand, Indonesia, and especially Malaysia have been focusing energy on the cultivation of the oil palm tree (which is not native to those regions) for use as a biodiesel fuel and as a possible alternative to the use of fossil fuels. Ironically, what appears to be environmentally sound may not be, since large sections of natural forest are clear-cut and replaced by oil palm plantations, possibly leading to significant environmental problems.

—Kevin M. McGeough

grows in bunches, which can become quite heavy, between 22–88 pounds (10–40 kilograms); in ancient times, probably closer to 22 pounds would have been normative. The fruit is removed from the tree by the bunch and then must be left to ferment in order to be soft enough to separate the individual fruit. The individual fruit is red in color and resembles plums.

Scholars are not sure precisely how palm oil was produced in ancient times but can reconstruct production techniques based on more recent practices. In the so-called soft oil technique, the fruit is separated from the bunch as soon as it is loose enough to do so. It is then boiled in water until the flesh is softened (a process that would take as long as four hours and require a substantial amount of firewood). The cooked fruit is then placed in a vat and pounded into a pulp. Water is added to the pulp, which causes the oil to separate and float to the top of the vat, where it is then skimmed off. This process is repeated over and over until all of the reddish oil has been removed. The separated oil is then boiled again to remove any extra water, a process that removes the reddish color from the oil and also uses a large amount of wood.

The more likely technique to have been used in antiquity is the so-called hard oil technique whereby the fruit is left on the bunch for a longer period of time. This removes the need to boil the fruit to soften it and also does not require

the substantial amount of firewood necessary in the soft oil technique. The fruit is mashed in some sort of container that allows the oil to drain out. This is done over and over again until all of the oil has drained out. Then, the oil is boiled to remove any excess water, changing the color from red to white. There is a significantly lower yield from the hard oil technique, but it was probably still preferred given how much wood would have been consumed in the fires necessary for the soft oil technique.

IDENTIFYING MANIOC USE THROUGH EXPERIMENTAL ARCHAEOLOGY

Given that manioc does not survive well archaeologically and that the tools that could be used for manioc exploitation could also be used for other activities, archaeologists had to devise methods to determine when manioc use began in ancient America. Dave Davies has attempted to solve the problem of identifying manioc use through experimental archaeology. Taking obsidian tools, such as those that would have been used in the ancient Americas, he used them to grate manioc. After the grating was finished, he examined the tools for distinctive wear marks left on the tools from the act of grating. What he found was that given the peculiarities of manioc, a distinct wear pattern could be identified on the tools that he used to grate manioc. This same wear pattern could be found on ancient obsidian tools, thus providing strong evidence for manioc exploitation even when no remains of manioc were found.

—Kevin M. McGeough

Manioc

Manioc is a tropical root plant that is indigenous to the Americas. There is no scholarly consensus regarding where manioc originated. In modern times the widest variety of manioc species are found in Brazil. The earliest samples of manioc that have been recovered archaeologically come from the Casma Valley in Peru, dating to 1785 BCE. Scholars are relatively certain that manioc was being exploited in South America prior to that date, even though evidence is lacking. Manioc is not preserved well in a tropical environment, so the evidence for its purposeful use must come from the analysis of artifacts that may have been used in its exploitation and production, such as ceramic platters or graters. Since these types of tools may be used for other purposes, any conclusions drawn about early manioc exploitation are far from certain.

The plant goes by many names—the most common other names are yuca and tapioca—and requires secondary processing before it can be consumed. Most important are detoxifying procedures that are necessary to prevent poisoning. The processed material can be made into a type of meal or mush, bread, or tapioca pudding. It can also be roasted or fermented into an alcoholic beverage. Manioc is not particularly high in protein. However, crop yields are high, and the leaves can also be ingested, making manioc cultivation a relatively profitable enterprise.

Manioc. (Angela Sevin)

There are two major types of manioc: sweet and bitter. Sweet manioc grows relatively quickly and is very suitable for eating. Bitter manioc takes longer to grow and is more likely to become poisonous (although it can be detoxified). However, bitter manioc is more resistant to natural pests and drought and provides certain soil benefits. Scholars initially took manioc to be quite destructive to soil since it was found in regions that had suffered from severe soil degradation (claims such as this often appear in older books). Further analysis has shown that manioc was found in these areas not because it had destroyed the soil but because it was one of the few crops that could grow in this soil.

The Domestication and Spread of the Chicken

Evidence for the history of chicken domestication is rather patchy. Bird bones are small and fragile and thus are often poorly preserved and more frequently missed during excavation. Domestic fowl were often kept by ancient societies not only for meat and eggs but also for rituals and sacrifices and the cocks for fighting.

The chicken was domesticated from the jungle fowl (*Gallus* sp.). Of the four wild species, the red jungle fowl (*Gallus gallus*) is most closely related to the domestic chicken and is likely to be its ancestor. Its distribution includes much of eastern India, Bangladesh, most of mainland and island Southeast Asia, southern China, and Henan. In the 1990s genetic evidence suggested a single origin, Thailand, for domestic

Southeast Asian red jungle fowl. (David Hosking/Corbis)

fowl, but more recent genetic studies indicate two separate foci of domestication, China and India.

Diaotonghuan and Xianrendong caves, south of the Yangzi, were occupied from the late Pleistocene by people who exploited wild resources, including chickens; possibly in the later stages of the occupation these were domesticated. Fowl bones are known from a number of sixth- or fifth-millennium Chinese sites, including Cishan north of the Yellow River. It is not clear whether these were from wild or domestic birds, but it is significant that they are outside the range of wild red jungle fowl. Probably by the fourth millennium, domestic chickens were well established in China. Chickens were introduced to Korea from China and then to Japan during the Yayoi period. Chickens must have made a welcome addition to the limited range of Chinese domestic animals, mainly pig and dog.

Jungle fowl were domesticated considerably later in South Asia. It is disputed whether their original distribution extended into Sindh; there seems no doubt, however, that wild jungle fowl were present in the eastern region of the Indus civilization (2600–1900 or 1800 BCE), and they were probably domesticated there. It is likely that the development of urbanism encouraged the domestication of chickens, since they were animals that could be kept for meat (as well as eggs) in the restricted space available to town

► THE CHICKEN IN SOUTH AMERICA

It has long been suggested that there were pre-Columbian contacts between Pacific islanders and the inhabitants of South America. One reason is that chickens were being used by the Incas when Pizarro arrived in Peru; it seemed improbable that these could have spread to Peru so rapidly from the European settlements in Central America and the Caribbean established a few decades before. It was suggestive that chickens were kept by the first colonists of the Pacific who had reached Hawaii and Easter Island sometime between 400 and 800 CE. In addition, the unusual blue color of the eggs of some American chickens was paralleled in China and Easter Island. Nevertheless, irrefutable proof was lacking.

Recent work, however, provided the evidence to clinch this hypothesis. The DNA of a chicken bone from El Arenal-1, on the Arauco Peninsula, Chile, analyzed in 2007 proved to match that of chickens from Tonga, Samoa, and Easter Island, revealing that the South American Aracauna breed of chicken was of Polynesian origin and had been introduced by or before the fourteenth or early fifteenth century CE, well before the arrival of the first Europeans in the Americas.

—Jane R. McIntosh

and city dwellers. Chicken bones have been found on many sites of the Indus civilization, including the cities of Mohenjo-daro and Harappa and the towns of Rupar and Kalibangan in the east and Lothal, Rojdi, and Surkotada in the west. These birds were larger than wild jungle fowl, emphasizing their domestic status. There are also Indus figurines and images on seals depicting chickens and a sign in the Indus script that is a logograph of a chicken. The presence of domestic fowl is also claimed at Neolithic Gufkral in Kashmir, dated to the late third or early second millennium BCE and perhaps an introduction from the Harappan region.

Numerous chicken bones were found in the third-millennium Middle Ganges settlement of Damdama. These were probably from wild jungle fowl but indicate that the birds were an important economic resource at this time. During the

second millennium, domestic chickens began to be kept in many parts of the subcontinent.

The spread of chicken to West Asia, Africa, and Europe seems to have involved birds from both China and India. From China, chickens were introduced to central Asia possibly before 3000 BCE. From here steppe nomads probably introduced them to both eastern Europe and the Iranian plateau. Chickens are known from a few third-millennium sites in Romania, Turkey, and Greece and in the Bronze Age German sites of Wüste Kunersdorf and Kyffhäuser cult caves.

From South Asia, small numbers of chickens reached West Asia and then Egypt in the third and second millennia, but they remained rare. A Sumerian literary reference to birds with a carnelian beard from Meluhha (the Indus) suggests that the Harappans first brought chickens to Mesopotamia. Chickens probably continued to be exotic goods brought in by traders. Chicken bones have been reported from late third-millennium Tel es-Sweyhat in Syria and late Bronze Age Tel Michel in coastal Canaan.

In Egypt the evidence is purely from artistic and literary sources. These include a graffito of a chicken in an Egyptian temple around 1840 BCE, references to chickens brought back to Egypt from military campaigning in the Levant during the Eighteenth Dynasty (1539–1292) and in the fifteenth century to birds that laid eggs every day, and an unmistakable cockerel drawn on an ostrakon from Tutankhamun's tomb.

By the later second millennium, chickens were being raised in Iran. The Medes adopted the cock as a symbol in the Zoroastrian religion. From Iran chickens were introduced to West Asia, where they are depicted on seals from the eighth century onward. The birds seem to have been kept at least in part for cock fighting and as sacrificial animals. Representations in Egyptian art appeared in some numbers from around 650 BCE, but chickens only became common in West Asia and Egypt during the Persian period. Chickens increased further in importance in Hellenistic times when several breeds are known.

Domestic fowl spread from West Asia into Anatolia and Europe, being known in Greece and Italy from the eighth century and becoming common by the sixth century. They were popu-

lar in the Classical world as sacrificial victims and in augury and more widely as a symbol of fertility. The Phoenicians or the Greeks probably introduced the chicken into Spain. The Greeks and Romans kept large breeds of chickens, some of which were imported into Celtic Europe, where chickens were kept in small numbers, providing mainly meat but also eggs in the spring.

Recent genetic studies suggest that chickens in Africa may derive from both South Asian and East Asian domestic lines. The same is true of chickens in Southeast Asia and Sri Lanka, reflecting the complex history of trade and migration in the Indian Ocean. It is likely that chickens were introduced to the Sahel belt of sub-Saharan Africa through trans-Saharan trade; the earliest evidence here is from the city of Jenne-jeno in the Niger basin, dated to 500–800 CE. Domestic chickens are known at Qasr Ibrim in Nubia from the fifth and sixth centuries CE; they may have been introduced from Egypt along the Nile Valley, from the Mediterranean via the Red Sea, or from India by sea.

Indian Ocean trade in the first millennium CE is also likely to have introduced chickens from India to eastern parts of sub-Saharan Africa. They are known at Iron Age sites in East Africa (Manekani and Chibuene in Mozambique) and South Africa (Ndongondwane in Natal) in the eighth century CE. At the important coastal trading site of Manda in East Africa, chickens become an important domestic animal from the ninth century CE.

Given the distribution of wild jungle fowl, we would expect chickens to have been domesticated in Southeast Asia; however, this seems not to have been the case. Bones at Khok Phanom Di in Thailand, dated after 2000 BCE, belonged to a nonlocal species of jungle fowl. Similar evidence comes from the contemporary site of Nong Chae Sao. By 2000 BCE, farming communities whose domestic animals included chickens were also appearing throughout the Malay Peninsula.

Until recently it was thought that the farmers and fishers who colonized the islands of the Pacific originated in Taiwan and the Philippines, but the most recent evidence indicates a more southerly origin, from Southeast Asia through

Indonesia. The inclusion of domestic chickens among the staples of the colonists' economy (along with dogs and pigs) shows that the chicken was an established domesticated animal in island Southeast Asia before 1500 BCE despite the paucity of evidence in that region itself. These colonists reached Samoa in western Polynesia by 1000 BCE and spread chickens throughout the Pacific, with the exception of New Zealand. New Guinea was bypassed in this movement and probably acquired domestic chickens at a later date.

The First Wine and the Origins of Viticulture

It is difficult to identify the earliest wine since, unlike beer brewing, wine is created through natural processes. The grapes do not have to be cultivated, nor does fermentation need to be encouraged by human intervention in order for wine to be created. The juice of grapes simply needs to come in contact with airborne yeast for fermentation, a relatively quick process, to take place. Thus, the earliest wine may date to the earliest consumption of grapes, a practice that can be traced back at least 35,000 years in France.

The first positive evidence for wine, however, appears in the archaeological record much later, in Iran. There is evidence that wine was consumed during 5400–5000 at the site of Hajji Firuz Tepe. Amphorae (large ceramic vessels) excavated from Godin Tepe in Iran preserved wine resins that demonstrate a sophisticated knowledge of wine production. At the bottom of these amphorae a reddish deposit, caused by

WINE—MEDICINE OR POISON?

The modern debate over whether wine is a healthy dietary supplement or a substance that destroys both body and mind has roots far back in antiquity. It seems that for as long as wine has been produced, people have debated whether or not it should be drunk. Vedic texts from India praise wine as an important part of a healthy diet during the cold winter seasons. Wine is said to increase strength, energy, and courage. However, the Vedas also warn of the ill-effects of too much consumption: drowsiness, obesity, impotence, and even leprosy. In general, the intoxicating properties of wine were seen in a negative light by the authors of the Vedas (as opposed to the positive intoxicating effects of soma). The ancient Egyptians were similarly undecided about whether wine was healthy or unhealthy. In tomb reliefs, wine is used as a symbol of positive abundance. Yet in some of these reliefs, diners at banquets are depicted as vomiting from too much wine. An Egyptian wisdom text called *The Admonition to Schoolboys* warns of the negative consequences of drunkenness.

—Kevin M. McGeough

tannin and tartrate crystals, was preserved, clear signs of wine consumption (as opposed to merely grape juice consumption). Since vines provide numerous types of foodstuffs (such as fresh fruit, raisins, and vinegar), the finds at Godin Tepe are important evidence for early consumption of wine per se.

While cultivated vines are not necessary for the production of wine, human crop management is important for producing a stable crop of grapes. The domestication of vines is quite different from the domestication process for cereals, which is based on seed selection. Vines are reproduced through cuttings and grafting (the connection of two living pieces of plant tissue so that they will grow as one plant). Many varieties of vines are dioecious (meaning that there are male and female vines); hermaphroditic vines are the easiest to cultivate, so much of the domestication process involves crossbreeding vines to facilitate reproduction. Determining where vines were first domesticated is very difficult since vines grow naturally throughout the Medi-

terranean and between the Black Sea and the Caspian Sea. Today, the greatest diversity of wild vines is found between the Caucasus and Armenia, so this region may be a good candidate for the first domesticated vine although there is no positive archaeological proof of this.

While scholars are uncertain of the location of the first domestic vines, they are able to trace the spread of domesticated vines throughout the Old World. At the site of Trialeti, Georgia, in the former Soviet Union, vine cuttings were found in a silver sheath (decorated with vine buds) dating to about 3000 BCE. Cuttings dating to approximately 3000 BCE have also been recovered from southern Spain, indicating vine domestication that developed independently of eastern Europe and Asia Minor. Third-millennium Mesopotamia had vines in the north, yet wine never overtook beer as the dominant drink of the region. In Anatolia, however, the climate was well suited for viticulture, and wine distribution and wine making were important industries throughout the Bronze Age. Certainly by 3000 BCE, vines had been imported into the southern Levant (Canaan). These Canaanite vines are clearly imports since they do not naturally grow in that region. Farther south in Egypt (another region where vines do not grow naturally), vines had been imported during Predynastic time, as early as 3100 BCE. Vines may have been imported to the Indus Valley around 3000 BCE, but there is no evidence of wine consumption in this culture at all. Wine becomes prominent in Vedic India sometime between 2000 and 1000 BCE; Vedic culture was better situated ecologically in the Indian subcontinent than the Indus Valley for wine production. By 2500 BCE, domesticated vines were well established on the Greek mainland and on some of the Greek islands.

Planting a vineyard was a long-term process. Vines typically do not bear fruit for the first 3–5 years after planting. They require constant attention and must be judiciously manipulated with cuttings and graftings; if not, the vines will revert to wild form quite quickly. Vines cannot easily be removed; after a vine has been planted, it is very difficult to make the land arable for other types of crops. Vines will, however, last for generations, making them very valuable once they have been properly established.

Minoan storage jar (known as a pithos) found at Phaistós on the island of Crete. Ceramic containers were used to store oil, wine, and food throughout the ancient world. (Corel)

The manufacturing of wine is relatively simple. All that is really required is an appropriate storage container for the fermentation process. Egyptian tomb reliefs depict ancient wine-making practices; similar equipment found throughout the Mediterranean suggests that the practices were relatively standard. Grapes were first crushed to yield free-running juice. The remnants of these grapes were put into sacks and pressed (usually with heavy equipment) to release more juice. It is unclear when exactly the grapes were allowed to ferment (the timing probably varied from vintner to vintner). Usually, though, fermentation took place in large amphorae where air was deliberately kept out.

Wine production and distribution took place at a number of different levels, from large royal enterprises to small-scale household production. The Hittites had numerous laws dealing with the appropriate distribution practices of wine; there the practice seemed to be highly regulated. At the site of Ugarit, on the Syrian coast and under Hittite hegemony during the Late Bronze Age, real estate contracts stipulate that vineyards were considered part of the individual's land. At that same site, which clearly allowed small-scale vintners to practice the craft, the palace engaged in its own wine production at large agricultural estates called *gittu*. Similar royal practices are evident among the Minoans of Crete. The palaces of the Minoans (especially the largest, Knossos) had large magazines (storerooms) filled with gigantic pithoi (ceramic vessels) embedded into the floor that once held wine. Linear B texts detail the distribution of wine by the palace, and one of the few signs that can be identified in Linear A (the untranslated language of the Minoans) is the sign for wine.

Wine production in Egypt is extremely well attested. There, wine was considered an elite beverage (as opposed to the lower-class beer that most Egyptians had access to). Vines were grown in small walled gardens. Olives were grown in a similar fashion and often in tandem with grapes. Since wine was frequently deposited in tombs to accompany the dead into the afterlife, many intact vessels have been recovered. The earliest examples are the approximately 700 amphorae that filled three rooms of King Scorpion's Predynastic tomb at Abydos. Many of these vessels were labeled, listing where the wine had come from. The wine recovered from King Tutankhamun's New Kingdom tomb preserved even more information. These wine labels listed information such as the location of the vineyard, the owner of the vineyard, the chief vintner's name, and even the year of bottling. It seems that 1345, 1344, and 1340 BCE were particularly good years for Egyptian wine.

Beer

In ancient Mesopotamia and Egypt, beer was an essential part of the daily diet. It was drunk by all classes of people, was used in all manners of ritual, and acted as an ingredient in many medicines. It has been suggested that the transition of hunter-gatherer tribes to settled farmers was due to their desire to grow grain, not for bread but for beer. This is unlikely, however appealing it may sound as a theory. Regardless, beer production appears very early in both the artistic and archaeological records of the Near East and Egypt. Depictions of people drinking beer in Mesopotamia appear as early as 3500 BCE on cylinder seals. At the site of Hierakonpolis in

Egypt, the earliest brewery was discovered dating to the Naqada II period (around 3500 BCE).

Beer in ancient Mesopotamia and Egypt was made using grains such as emmer and barley. Beer could be flavored using a variety of additives such as honey, dates, herbs, and spices. There were a couple of different methods of brewing beer in the ancient world. The first involved the fermentation of beer bread. A loaf of bread was made and partially baked (fully baking the bread kills the yeast). The bread was then crumbled into a vat of water. The live yeast in the bread caused the water and bread mixture to ferment. Another method of brewing beer involved creating malt, which involved soaking grain in water for several days until it started to sprout. The malt created the sugars on which the yeast feeds during fermentation. The malt was then crushed and mixed with regular grain before being sieved to remove the indigestible chaff (the papery shell enclosing the seed). This malt mash was put in a vat of water, yeast was added, and the vat was allowed to sit for several days. Fermentation of these bread and water or malt and water mixtures resulted in beer. Unfortunately, beer could not be stored for long periods of time, as after a while it turned very sour. So beer, like bread, had to be made on demand.

Beer was a staple of the ancient diet. Every class of people from kings to peasants drank beer. In many cases beer was safer than drinking water because its alcohol content killed off many bacteria. It was also full of carbohydrates, vitamins, and calories, which made it nutritious as well as thirst-quenching. Beer was drunk in two forms, strained or unstrained. The Egyptians drank their beer strained, but the Mesopotamians seem to have preferred their beer unstrained. Carvings on cylinder seals from as early as 3500 BCE show people drinking their beer through long straws. These depictions of beer drinking almost always show two or more people drinking from a large vat, suggesting that it was a social activity. The straw, often with a little sieve at the bottom, prevented the drinker from ingesting the chunks of malt or beer bread floating in the beer. The straws were made out of a variety of materials from a simple hollow reed to metals such as copper and gold. The

An ancient Syrian in Egypt drinking beer with a straw. Egypt, Eighteenth Dynasty, about 1350 BCE. (Bettmann/Corbis)

tomb of Lady Puabi at Ur (roughly 2600 BCE) contained a four-foot-long gold straw with a lapis lazuli strainer at the tip for drinking beer.

In both Egypt and Mesopotamia there was no monetary system, so wages were frequently paid using food and other goods, including beer. Institutions, especially temples and palaces, had large baking and brewing operations to make the bread and beer rations for their workers. In ancient Egypt a normal daily wage for a worker consisted of ten loaves of bread and two jugs of beer. It may sound like a lot, but this food also had to feed the worker's family. The higher the status of the worker, the more bread and beer he received. Beer was dispensed in pottery jars that were roughly equal in size, ensuring that everyone got an equal portion. Prices were often expressed in units of bread and beer, even though other commodities were used in the actual transaction. In Mesopotamia, workers were paid in raw grain that they then turned into bread and beer at home. Brewing beer and baking bread fell into the sphere of domestic chores done by the women of the household in Mesopotamia. Some women were able to take these domestic skills and turn them into a business as tavern owners.

Taverns were common in Egypt and Mesopotamia. In Mesopotamia, brewers and tavern owners were often women. The Code of Hammurabi (roughly 1800 BCE) refers to tavern owners as specifically being women. Literature from ancient Egypt and Mesopotamia links taverns with intoxication, rowdiness, and debauchery despite the fact that ancient beer had a relatively low alcohol content. A genre of literature from Egypt called the instruction text gives advice on how to behave in order for Egyptians to advance their careers. Many of these texts warn against drinking too much beer or going into taverns, even if accompanied by your boss.

Beer was prescribed as a medicine in ancient Egypt and Mesopotamia. Although it could be used alone, more often it was used as a base into which other active ingredients were mixed and then applied to a wound or ingested. Apart from taking the edge off, beer may also have had real healing qualities because certain bacteria, which flourished in grain stores, are similar to those

➤ BEER AND MYTHOLOGY

In Mesopotamia, Ninkasi is the patron goddess of beer. She was charged with making beer for the gods. In Egypt, Hathor was considered the goddess of beer because of her role in the myth of the destruction of mankind. In the myth, the god Re, ruler of earth, learns that mankind is plotting to rebel against him. As punishment he sends Hathor, usually a peaceful goddess, to kill the rebels. However, Hathor threatens to kill all men. In an effort to save the innocent, Re causes the land to be flooded with beer, which he stains red to make it look like blood. Bloodthirsty Hathor falls for the ruse, drinks the red-colored beer, gets very drunk, and becomes docile again.

—Vanessa Smith

used to make modern antibiotics. A swig of beer could give a boost to the immune system, as beer production did not use very high temperatures (unlike the baking of bread), which killed the antibiotic bacteria.

—Vanessa Smith

Soma

In Vedic literature, Soma is a type of plant, a type of drink, and a god. These three aspects of Soma were probably not understood as separate elements but rather all mutual aspects. Soma is glorified in the Vedas, most notably in the Ninth Mandala of the Rig-Veda. Also called the Soma Mandala, this section of the Rig-Veda consists of

» HYMNS TO SOMA

The Ninth Mandala of the Rig Veda is filled with hymns about Soma. Here, in Ralph T. H. Griffith's translation from 1889 (outdated but capturing the spirit of the hymn), some of the powers of Soma are described. What follows is from Hymn IV:

- “1. O Soma flowing on thy way, win thou and conquer high renown;
And make us better than we are.
2. Win thou the light, win heavenly light, and,
Soma, all felicities;
And make us better than we are.
3. Win skillful strength and mental power. O Soma,
drive away our foes;
And make us better than we are.
4. Ye purifiers, purify Soma for Indra, for his drink:
Make thou us better than we are.
5. Give us our portion in the Sun through thine own
mental power and aids;
And make us better than we are.
6. Through thine own mental power and aid long
may we look upon the Sun;
Make thou us better than we are.
7. Well-weaponed Soma, pour to us a stream of
riches doubly great;
And make us better than we are.
8. As one victorious unsubdued in battle, pour
forth wealth to us;
And make us better than we are.
9. By worship, Pavamana! men have strengthened
thee to prop the Law:
Make thou us better than we are.
10. O Indu, bring us wealth in steeds, manifold.
quicken all life;
And make us better than we are.”

—Kevin M. McGeough

Ralph T. H. Griffith, *The Hymns of the Rig Veda* (London: E. J. Lazarus, 1889).

hymns about Soma. There it is compared to the sun and to fire and throughout the Rig-Veda is associated with immortality. Soma is so important in this literature that Wendy Doniger O'Flaherty asserts that Soma sacrifice and the results of ingesting Soma lie at the heart of the Vedas. By 800 BCE, however, references to Soma disappear, and the practice of ingesting Soma was no longer written about.

The precise identity of the plant is not made clear in the texts. The Vedas describe the plant as shining brilliantly and yielding a yellow liquid when pressed. It grows in the mountains but cannot be cultivated. Modern scholars have made many attempts to identify Soma. Given the hallucinogenic qualities associated with Soma, it has been variously suggested that it was a type of wine, cannabis, rhubarb, ephedra, or mushroom. It is unlikely that it was a type of alcohol since the production processes were not long enough to allow fermentation, alcohol is referred to by other terms in the Vedas, and generally, alcoholic intoxication is not described in a positive light in Vedic literature. Rhubarb had been suggested since later traditions explicitly describe the substitution of rhubarb for Soma (of course, if rhubarb is described as a substitute for Soma, it hardly makes sense to assume that the two plants are equivalent). Plants that yield ephedra would have been available to the ancient priests, and ephedra does provide the type of stimulation that is described in the Vedas. The properties of hallucinogenic mushrooms are more consistent with the Vedic descriptions of Soma (both its appearance and its effects), and this is the most widely accepted identification, although the contention that Soma was a type of mushroom cannot be proven with certainty.

The traditional etymology of the word Soma states that it means “pressed thing.” While traditional etymologies often do not actually reflect the true linguistic origins of a word, in this case the etymology reflects the typical production techniques used for Soma according to the Vedas. The plant is submerged in water and then removed and placed on a board covered in hides. Rocks are then used to pound the juice out of the plant. The juice is then forced into wooden filters. After filtering, the juice may have been mixed with a number of other substances, in-

cluding milk, barley, honey, or water. Priests then drank the concoction, feeling the hallucinogenic properties, which from a theological perspective gave them divine attributes or allowed them to experience divine qualities.

■ Introduction: Food Production

Food-production techniques show remarkable similarities throughout the world in the period from 4000 BCE to 1000 BCE. This is because there are certain steps in the manufacture of food that are essential in order to supply the food and process it in a way that is digestible (and palatable) to humans. The main types of food production that are identifiable in the archaeological record of this era include hunting and gathering/foraging, pastoralism, and agriculture, all of which probably have their origins prior to 4000 BCE. The material culture associated with these activities displays some level of homogeneity. Hunters usually use stone projectile points (arrows or spears) as well as stone tools that can be used to process the meat of dead animals. Agriculture requires tools for planting and harvesting (such as sickles and plows), tools for processing grains since the hull is indigestible (such as stone grinders and pounders), and tools for baking, cooking, or fermenting the produce. When excavating a site, archaeologists look for clusters of these kinds of tools in order to identify the food-production techniques that were used.

The similarity in foods eaten and tools utilized led nineteenth-century historians to argue for two opposing explanations. One group of historians believed that all cultures develop along similar lines, going through similar stages, much as children reach different developmental stages

on their way to adulthood. This theoretical framework is referred to as unilinear cultural evolution. Another group of historians argued for an explanation that is incompatible with unilinear evolution, that innovations are invented once and then spread throughout the world by travelers, traders, and conquerors. Scholars who agreed with this theory (called diffusion) attempted to trace where agriculture was first invented and the route of its spread around the world. It was difficult for scholars to reconcile these views. There was evidence that could support both theories, but there were also problems with each. Historians (usually) no longer argue that one or the other of these theories was the sole operating mechanism behind the development of world food-production techniques. Both viewpoints seem to have some validity in certain contexts (e.g., it seems clear that rice cultivation spread from China to the rest of South Asia; however, that agriculture itself developed independently in such regions as the Americas and the Near East). However, hints of these theories can still be found in the reconstructions of the past made by many archaeologists. These biases are important to detect since this argument still lingers on as the subtext beneath many discussions of the development/spread of food-production techniques.

African Agriculture—On the Savannah and in the Forest

The origins of agriculture in Africa (outside of Egypt) are very poorly understood; not enough archaeological work has been done to truly understand the issue. Most scholars assume that at some point during the period between 1000 BCE and 300 CE, agriculture took root in parts of Africa, both on the savannah and along the forest margins. The general distinction between savannah and forest agriculture has survived to the present day. Different temperatures as well as the different amounts of rainfall, sunlight, competing plant life, and soil types in these regions forced the inhabitants to employ different agricultural strategies and make different choices about which crops to plant.

The current working hypothesis on the origins of African agriculture is that it began on the savannah. Most indigenous African plants were first domesticated in the savannah. Likewise, im-

Sorghum growing near Masvingo, Zimbabwe. (Corel)

ported plants also seem to have first adapted to the savannah before adapting to the forests. As population or cultural pressures (such as warfare, competition, or senses of territorial ownership) developed, people were forced to plant crops in areas that were increasingly less suitable until they were planting on the margins of the forest (and in some cases within forest zones).

African savannahs are (and were) large stretches of relatively flat land dominated for most of the year by the huge cloudless sky. Temperatures remain constant throughout the year, usually averaging between 60 and 75 degrees Fahrenheit. Rain falls in the winter but generally not in the summer. The land is covered by wild grass, and there are shrubs and a few trees dotting the countryside, plant life that can survive even given this seasonal variation in rainfall. Although most plants die in the summer, the underground roots survive. Herd animals roam the savannah subsisting on this vegetation; predators such as lions survive on these herd animals. Crops grown on the savannah vary from region to region. The most important include pearl millet, sorghum, and rice. Other crops grow on the savannah as well, although it is more difficult to identify which may have been in use in this period; certainly seeds and nuts were exploited that early.

The forests and forest margins are not as well adapted for agriculture, but most scholars believe that agriculture began in the forests of West Africa and the Congo during this period.

➤ MALARIA

Malaria was a significant problem in antiquity and undoubtedly limited the ability of humans to make use of significant stretches of sub-Saharan Africa for farming or cattle rearing. As Africans began living in settled communities with larger populations, they increased their chances of spreading malarial infections. Similarly, human clearance of forest land left swamps and small pools of standing water, the ideal habitat for insects, especially the tsetse fly. Eventually, communities were able to develop immunity to malaria but at a significant cost of human life. From central and western Africa, malaria spread across the globe. Mesopotamian texts associate plagues with the god Nergal, and it is likely that some of these references are to malarial plagues. Vedic texts from India describe plague symptoms that are similar to those associated with malaria. Ancient Chinese medical texts (such as the *Nei Ching*) also discuss plague symptoms similar to the fevers associated with malarial infection. The spread of malaria may be seen as one of the unintentional side effects of sedentary farming in Africa and contact with outside regions.

—Kevin M. McGeough

Coffee, kola, and akee apple are well suited for forests, but it is doubtful that these played an important role in this era's subsistence regimes. Rice can thrive in this environment if enough effort is expended by farmers to provide proper conditions. Arguably the most suitable crop for the forests was the yam, which can thrive in a number of situations. No positive evidence for yam domestication in this period has yet been discovered; unfortunately, yam remains will not survive well archaeologically in this region, so a lack of evidence cannot be taken as proof that yams were not domesticated. Oil palm may also have been important on the margins of the forest but cannot survive in the deep forest. Oil palm kernels dating to this era have been recovered from archaeological sites in West Africa, but the context has not been clear; these may have been from wild trees.

Even though plant domestication seems to have taken place first in the savannah regions, there does not seem to have been a central location where this innovation first appeared. Had agriculture developed in one location first and then spread elsewhere, we would expect to find only a few genera of species used as crops. In fact, the evidence shows that a variety of local plant types in a variety of different areas were incorporated into early agriculture. Thus, agriculture seems to have developed independently in different areas of Africa.

Egypt and Wheat

Ancient Egypt developed and flourished as a result of the Nile River. The presence of the Nile allowed the Egyptians to cultivate emmer wheat (*Triticum dicoccum*) in a manner that yielded

vast surpluses of grain. Emmer wheat was already being cultivated by the Naqada I period (ca. 4000 BCE), having been introduced already domesticated into the region around 5500 BCE. At sites in northern Egypt of the contemporary Maadi culture, store jars full of wheat have been found. Wheat cultivation allowed the development of the complex culture that would become Dynastic Egypt and later would make Egypt the breadbasket of the Roman empire (after the introduction of durum wheat, *Triticum durum*, in the Ptolemaic period).

Cereal agriculture was the economic basis for the growth of Old Kingdom Egypt (2686-2125 BCE). Wheat and barley thrived in the Egyptian environment. One of the key problems in primitive agriculture is salinization of the soil. In many places this is dealt with by focusing on crops such as barley that are salt tolerant. In the fertile Nile Valley this was not necessary. The annual inundation of the Nile flushed out any of the accumulated salt in the soil, making the need for salt-tolerant crops unnecessary. Instead, the Egyptians were able to focus on wheat.

Like everything about Egyptian culture, subsistence strategies focused on the Nile and its annual cycles. The Nile would flood every July and August, and sowing would begin immediately after the flooding ceased in September. The wheat grown was a variety that matured during winter and was harvested during the spring before the heat and dryness of an Egyptian summer could damage it. This left the summer months for other tasks, such as the major public works and monuments built during the Old Kingdom. The strong centralized authority that developed during the Predynastic period (4000-3200 BCE), the Early Dynastic period (3200-2686 BCE), and the Old Kingdom was ideally suited for this sort of agriculture. The government would collect surplus grain (which was usually guaranteed given the extreme fertility of the Nile alluvium) that would be stored in case of low floods (disaster relief) and redistributed as rations during the off seasons when farmers were likely working as laborers on major projects. The government would also arbitrate in the typical sorts of grievances that are common among farmers (property lines and ownership and the use and maintenance of canals, for instance) and provide

security. Local governments that were subservient to the central government would have been responsible for maintaining the irrigation systems used in order to keep as much land under cultivation as possible.

The technology available to the Egyptians was primitive but effective. Ploughs were drawn by yoked cattle to break up the soil. Seed was then scattered, and the cattle were used to tread it in. Harvesting was done (even into the Late Bronze Age) using flint-bladed wooden sickles. The ears of grain were then collected in baskets for threshing, which was done by throwing the grain on a threshing floor where cattle, sheep, or goats were driven to tread out the grain. The grain was then winnowed and sifted by hand to remove the chaff and then was stored in granaries. When needed for food, the grain would have been ground into flour and used to bake any number of different forms of bread and cakes.

Mesopotamia and Barley

Early Mesopotamian farmers had access to both domesticated barley and wheat, but barley dominated crops growing in this region in antiquity. This stems largely from the nature of the Mesopotamian climate and topography. The annual flooding of the Tigris and Euphrates rivers comes

too late for early crops and too early in the year for late crops. As a result, the only way to grow crops in the region is using irrigation agriculture. In Egypt, the Nile's annual inundation washed the salt out of the soil. In Mesopotamia, reliance on artificial irrigation meant that salt built up quickly in the soil. The salt-resistant nature of barley, however, made it a viable crop in this environment. Despite this tendency of the soil to become saline, it is highly fertile, and Mesopotamian yields of barley, according to Herodotus and Strabo, verged on modern yields of grain in the most fertile of Canadian wheat fields. Barley was so important a commodity to the ancient Mesopotamians that it was used as a currency, and in the Law Code of Hammurabi, barley is often used alongside gold as a standard for assessing values and penalties.

About 2.4 acres (1 hectare) of land was required to raise enough barley for subsistence in ancient Mesopotamia. This would mean that during the Late Uruk period (when the city of Uruk was at its peak size) the city would have been surrounded by 3.7 miles (6 kilometers) of farmland. This would mean that many farmers living in the city would have had to walk for more than an hour to reach their farm plots.

Thanks to numerous documents preserved on clay tablets, a great deal is known about the way that barley was grown in ancient Mesopotamia. For instance, the Sumerian Farmers' Almanac, which dates to about 1700 BCE, gives elaborate descriptions of the process, including details about how far apart to space the furrows, how much seed to plant, and how one should care for one's agricultural tools. The agricultural calendar was again closely tied to the local climate and topography. In the late summer, fallow land was well watered and then broken up using shod oxen. The land was then leveled out by hand using hoes. Then the soil was plowed with a seed plow pulled by donkey or an ox, which allowed for the sowing of seed and the digging of furrows in an organized fashion, unlike the broadcast sowing done in Egypt. The bulk of the land was sown with barley seeds, although some smaller allotments were sown with wheat and other crops. The standardized spacing and amount of seed made it easier to weed and irrigate than would have been possible had the seed

been broadcast sown. This constant weeding and maintenance of the irrigation canals, levees, and drainage ditches would have gone on from late summer through late April or early May, when the barley would be ready for harvesting. During this time the fields would be deliberately flooded three to four times. At harvest, the crop was cut using either a flint or ceramic sickle and was stacked for threshing. Threshing was done by driving carts or dragging threshing sledges over the grain. It was then hand-winnowed to remove the loosened chaff. Out of each measure of barley harvested, the Mesopotamian farmer could expect to feed about 16 percent to his animals, use about 10 percent for the next season's sowing, and lose about 25 percent in storage.

Irrigation in Mesopotamian Agriculture—Benefits and Problems

Babylonia was a land of sharp contrasts, cultivation giving way to desert at the farthest point that water from rivers and canals could reach. Irrigation was essential, because annual rainfall was generally below 100 millimeters, but even in the zone of rain-fed agriculture farther north, irrigation was important to increase productivity. Success in water management was therefore a crucial part of a ruler's duties. Mesopotamian kings proudly recorded the creation of dams, canals, and reservoirs, and the failure to provide or maintain water facilities could bring down a monarch or regime. Landowners and cultivators were legally responsible for the proper control and maintenance of the canals that supplied and the dykes that protected their lands, as law

codes and court records attest; there were stiff penalties for causing damage to a neighbor's crops or land by failing in these duties. Clashes over water rights provoked not only fights among neighbors but also wars between neighboring states. Land was plentiful and could be taken into cultivation by creating new canals and dykes, but this was only worthwhile in politically stable times. The importance of water management is also demonstrated by numerous school math exercises concerned with such matters as calculating the volume of water that needed to be released from canals or reservoirs to irrigate fields of certain sizes.

Since the annual inundation came just around harvest time, flood control was as important as irrigation. Dykes and embankments were built to contain the river at flood level and to protect existing irrigation works, and immediately before the floodwaters arrived, sluices and regulators were opened. The flood waters spread out over an area several kilometers wide, depositing the coarsest silt, richest in nutrients, on the levees, which were raised above the water table, encouraging good drainage; as the waters moved farther from the river, the silts deposited became progressively finer and more prone to waterlogging. Thus, the fertility of the land fell with distance from the rivers.

For plants cultivated on the levees, water was drawn directly from the river using lifting equipment. The simple shaduf devised by the Early Dynastic period was widely used, both to obtain water for immediate use and to raise it from lower to higher canals, reservoirs, and watercourses. The lower reaches of the Tigris, which flows at a lower level than the Euphrates, defied use for such simple irrigation but began to be exploited in the first millennium BCE when the Assyrians invented more sophisticated water-lifting equipment.

The backslopes and lower land were irrigated by canals, often several kilometers long, cut through the banks of the river levees. Regulators—brick-built structures that narrowed the watercourse and could be blocked or opened as required—allowed the water level in the river to be raised high enough to flow into these channels through sluices and outlets. Their slight gradient meant that the water flowed slowly along

► THE QANAT—UNDERGROUND IRRIGATION IN PERSIA

In Mesopotamian and Persian mythology, water was considered the source of being and a symbol for eternal life. Ancient Babylonian agriculture relied on aboveground irrigation systems that could be repaired, expanded, and enlarged. Open canals were not efficient in the very arid Iranian plateau, so people there relied on a system of underground water channels. These underground canals, called *kariz* or *qanat*, prevented the evaporation of water (a typical problem in surface channels). Constructing qanats gave Persians the opportunity to transfer underground water to villages and towns located away from sufficient water sources. A qanat was a main shaft excavated down to the permanent subterranean water level, usually at the base of hills or mountains. At approximately 50-foot intervals, shafts were dug to help remove material and maintain the qanat line. A qanat taps water that has seeped into the ground and channels it via straight tunnels to the land surface. To provide water to tree roots in orchards, contiguous gardens, or lining avenues, they built small open canals called *jubes* to move water in furrows or shallow ditches between rows of trees.

The oldest known qanat (located at Hailan-Aleppo in Armenia) is a profound channel 7.5 miles (12 kilometers) long that was still in use until the early part of the twentieth century. It is unclear what spurred the development of this type of water source. One theory is that qanats were originally improvised by miners in order to extract the water from the mines, and after a while, this system was gradually applied by farmers and spread all over the plateau of Iran. Later, the Achaemenid kings of Persia employed this system of water supply to the unirrigated regions of their territory. These underground channels, which could reach long

Qanats, underground canals for transporting water, in the desert near Isfahan in Iran. (Roger Wood/Corbis)

distances, gave people the ability to cultivate their own lands without great expense and trouble. Persians introduced qanats in Oman and Saudi Arabia (about 525 BCE), Egypt and Syria (600–500 BCE), and the Arava Valley in the Israeli Negev (during the Persian rule between 537 and 332 BCE).

these channels, and much was consequently lost to evaporation and seepage. Large networks of irrigation channels were constructed in the delta plain. Farther north in Babylonia's river plain the annual floods could sweep through with devastating ferocity, often damaging or destroying canals and breaking down the levees. The volume of silt carried and deposited by the river also

tended to clog up the river and canals, exacerbating the problem. Much effort was therefore put into creating dykes to protect the land and its irrigation works from the force of the waters. Early settlement concentrated particularly on the delta plain, but by the early second millennium BCE, developing technology, enhanced by the larger workforces that could now be mobilized,

enabled the Babylonians to better cope with the river-plain floods.

Irrigation exacerbated the naturally occurring problem of salt deposition on Babylonia's fields. Small amounts of salts carried down by the rivers from the sedimentary rocks of the north have over the millennia accumulated in the groundwater of southern Mesopotamia. The deposition of salts is greater in periods, such as that between 2350 and 2000 BCE, when the volume of water in the rivers is reduced. Intensive irrigation raises the water table, bringing this saline water close to the surface, where it is drawn up by capillary action, causing salts to accumulate in the subsoil and on the surface where water spread for irrigation also contains salts. When moisture is removed by evapotranspiration, the salts are deposited on the land, progressively reducing fertility. Strenuous efforts were made to drain away surplus water to prevent the water table from rising. Fields were left fallow, and therefore unirrigated, in alternate years, and affected areas were flushed with large amounts of water to leach out and carry away the salts. Eventually the land became too saline for cultivation. Many southern cities were abandoned in the second millennium BCE, and their inhabitants moved north or turned to pastoral nomadism.

Mediterranean Agriculture

The topography of the Mediterranean Sea region greatly influences agricultural practices. Mediterranean rivers are few and short in length, the land is mountainous and dry, and the region is spotted with thousands of inlets, bays, islands, and harbors that allow for shipping and the exchange of seeds, farm products, and technology. In times of drought and bad harvests, farmers from one region such as Greece could purchase grain from Phoenicia or Egypt. The lands surrounding the Mediterranean are framed by enormous geographical features: the Alps and related mountains to the north, the African Sahara Desert to the south, the deserts of Arabia and Syria to the east, and the Atlantic Ocean to the west. Agriculture in the Mediterranean region benefits from what is known as the Mediterranean climate, characterized by mild, rainy winters followed by hot, semiarid summers. In summer months, stationary weather fronts at the western (Atlantic) side of the Mediterranean block ocean air and allow very dry hot air from the Sahara to flow northward and bake the soil. In winter,

THOLOS TOMBS ON CRETE

The Greek word *tholos* means a rounded, bell-shaped, large funerary building with a vaulted roof constructed with stones in the shape of a beehive. Tholos tombs were great circular chambers cut into a hillside and entered by a corridor (a *dromos*). While the more famous tombs such as the misnamed Treasury of Atreus are found at Mycenae on the Greek mainland, the Greek archaeologist Stephanos Xanthoudides began excavating in 1904 in the southern Messara Plain on the island of Crete and found many circular tholoi similar in design to the Mycenaean type. Scholars continue to argue about the connection between the tholos tombs on Crete and the more famous examples at Mycenae unearthed by Heinrich Schliemann.

➤ AGRICULTURAL TERRACING

Remnants of agricultural terracing near Vathia, Greece.
(Karol)

Remnants of ancient terrace agriculture can be found in Mesopotamia, the Americas, Southeast Asia, and Africa. Farmers developed techniques of agricultural terracing in many places of the world, including the Mediterranean, where steep hillsides and mountains could not be plowed using traditional means. Terracing prevented erosion of soil and impeded precious rainwater from escaping. By slowing the speed of the movement of water, terrace platforms allowed sediment to settle, enriching the soil with nutrients. Terraces were constructed following the contours of hillsides using stones, clay, and dirt worked into steps or level channels that could be planted and easily drained.

—Jonathan L. Thorndike

weather fronts move in quickly from the Atlantic and bring waves of cold air, rain, and storms.

Indigenous plants that thrive in this climate need to grow quickly in the spring and fall and also be able to withstand long periods without rain in the summer. Many varieties of cereals, grains, and pulses (lentils) naturally adapted to this climate are also useful for human cultivation because they are annuals; that is, they live for only one year. These plants normally dry up and die during the hot summer. Because the cereals and grains live for only one year, they never get large or grow inedible woody stems. Grains such as barley and wheat devote most of their

energy to reproduction through seeds. The seeds are planted during the autumn months and thrive in the temperate rainy winter. They become dormant during the dry season and can be eaten or replanted with the return of the rains in the fall. Wheat requires somewhat more water and better-quality soil than barley and was thus a more valuable crop to Mediterranean farmers.

Besides barley and wheat, Mediterranean farmers also planted beans, emmer and einkorn (wheat varieties), pulses, olives, pomegranates, and grapes and produced related products such as olive oil and wine. The grains could be grown using available rain, while vines, vegetables, and fruit trees required irrigation.

The technology of Mediterranean agriculture evolved due to the need to break up the hard soil with wooden plows, which were sometimes covered with iron blades. Family farmers with small holdings plowed by sheer muscle power using hand tools such as spades. Aristocrats and wealthier Mediterraneans who owned larger estates could afford to feed oxen, which were used to pull plows, and keep more acreage until cultivation. In prosperous farming families, half of the acreage was uncultivated and crops rotated to avoid depletion of the soil. Even unplanted fields were plowed to increase the oxygen and vitality of the soil for the next year. Smaller family farms could probably not afford to sustain fallow land and were planted every year.

Agriculture in India after the Indus Valley Civilization

Agriculture in the Vedic period, which followed the Indus Valley civilization, was dominated by the transition from pastoralism to settled farming. In northern India (what is now Punjab and

later Uttar Pradesh and Bihar), new crops, technologies, and farming practices were introduced over several centuries. The use of iron was introduced sometime between 1300 and 1000 BCE. Prior to the introduction of iron, the use of wooden plows limited farming to areas with lighter soils, but iron-tipped plows allowed new areas with heavier soils to be cultivated. Iron axes supplemented the use of fire for the clearing of farmland in the Ganges River valley.

In the Rig-Veda, the most important literary source for the early Vedic period, barley is the most commonly mentioned crop. Other crops included sugarcane, seesamum (an oilseed), cucumbers, and gourds. The Rig-Veda does not mention wheat or cotton even though they were grown during the Indus Valley civilization. Land ownership was based on the tribe, and there is some evidence of changing ownership patterns during the Vedic period. Land was owned or assigned to members of the elite, although the labor was performed by hired laborers or slaves.

Domestic animals included horses, cattle, sheep, goats, buffalos, and, later, elephants. There has been a great deal of debate over the origins of the sacred cow in Vedic society. It is clear that cattle were used as one of the primary measures of wealth, and the Rig-Veda has numerous references to cattle raids. The Rig-Veda mentions animal sacrifice, and later Vedic literature specifically mentions cow sacrifice. It is only toward the end of the Vedic period that explicit prohibitions on cow slaughter began to appear.

Later in the period barley was replaced by rice and to a lesser extent wheat, and with the new crops came new systems of crop rotation and irrigation. The Indus Valley civilization may have used some irrigation, but large-scale irrigation became necessary with the cultivation of rice. Water for irrigation was drawn from rivers and wells. Irrigation channels were cut from rivers, and the Rig-Veda alludes to soil erosion along riverbanks. The need to efficiently draw water from wells led to the eventual invention of the Persian wheel, although it is unclear exactly when this occurred. The Rig-Veda also includes hymns devoted to the dangers of cows falling into wells, which were often little more than open holes in the ground.

Changing Subsistence Practices in the Indian Subcontinent

The development of ancient Harappan cities was possible because of the rich alluvial soils brought down by the Indus River. This river flooded its banks annually, bringing mineral-rich soil and a predictable volume of water to the vast agricultural lands that supported the urban population. The crops that were best suited for this type of subsistence regime were wheat and barley, and these two crops were the staple of the Harappan diet. Both of these crops are winter crops (*rabi*) in India and Pakistan. They are planted in the fall, watered by winter rains, and reaped before the floods that come in April. Neither crop would require extensive irrigation in the climate of the Indus Valley. However, given that the Indus River would have had to be constantly monitored and diverted to prevent flooding, it is likely that irrigation canals, water diversion channels, and dams may have helped ensure a stable flow of water to the crops. Harappan farmers used plows pulled by oxen to work their fields. Archaeologists have recovered numerous clay toy plows that replicate actual equipment, and a plowed field has been excavated at Kalibangan.

Oxen were not just used as beasts of burden. Animal husbandry was another key component of Harappan subsistence practices. Cattle (humped and unhumped animals) would have been a stable source of dairy products and possibly meat during times of crop failure or as a rare treat during festivals. Cattle are well suited for grazing in rocky terrain, allowing otherwise unusable land to be utilized in a subsistence regime. Images of cattle in Harappan art depict wide horned creatures, suggesting that the species utilized by the Harappans were either wild or newly domesticated. Water buffalo are less

► THE HARAPPANS AND CATTLE

Given the religious importance of cattle in modern Indian society, scholars have been keenly interested in the history of cattle rearing in the Indian subcontinent. For the ancient Harappans, cattle were clearly an important source of food and were also used as draft animals. In addition, cattle were also the sources of possibly vast personal wealth; an individual with a large herd was probably quite wealthy. Cattle appear prominently in Harappan art, especially in the glyptic art. Clay figurines of cattle and plows are common finds at Harappan sites. The pieces that are retrieved most often are legs that have been broken off of the body.

—Kevin M. McGeough

adaptable to their environment since they must be immersed in water or mud during the hottest months, so they were confined to the riverbanks. These animals do provide fatty, rich dairy products and would have been the most important source of dairy products for the ancient Harappans. Goats and sheep were kept in the cities as well as in the countryside, providing meat, dairy, and wool to the urban dwellers. Goats and sheep were (and still are) used as pack animals in the region.

The Harappans had access to other food resources to supplement their diet. Other types of crops included peas, vegetables, sesamun, and pulses. India and Pakistan are known for the abundance of spices that grow there. This was as true in ancient times as it is today, so it can be assumed that Harappan food would have been well seasoned. Honey, dates, and palm sugar were used as sweeteners. Fish and shellfish made up a large portion of the diet of the Indus Valley people, whose cities were all close to large water systems. Wild pig bones have been recovered from sites, indicating that these animals may have been hunted occasionally. There is no evidence for any sort of pig domestication. Many other wild animals were hunted as dietary supplements, including rhinoceroses and elephants.

Scholars are divided on when rice, sorghum, and pearl millet were introduced into the Indian subcontinent. It seems that the ancient Harap-

pans may have experimented with these crops, but at that time they would have been unsuitable for that region. They were better suited for planting in very wet areas, so the introduction of these crops allowed the monsoon regions along the Ganges River to be utilized as agricultural lands. They would have been planted during or immediately after the monsoon season and harvested in the fall. Over the course of the second millennium, settlements in the subcontinent shifted from the Indus Valley to the Gangetic Plain, and the cultivation of summer crops (*kharif*) such as rice, sorghum, and pearl millet provided the dietary staples.

Maize Crop in the Americas

When Christopher Columbus arrived in the Western Hemisphere, maize was raised by most of the Indians of the Americas; they considered maize the staff of life. Its cultivation extended from Canada in the north to Argentina and Chile in the south. The precise origin of domesticated corn continues to be a matter of debate to the present day. Some scholars claim that there exists a clear direct link between a wild grass called teosinte (*zea mexicana*) and the early varieties of domesticated corn. These scholars theorize that ancient Americans in gathering teosinte began to select more productive strains and through this process began to alter the genetic marks of the wild teosinte, leading eventually to production of domesticated maize. Yet there exists no archaeological evidence to substantiate this transitional evolution of teosinte.

In 1948 in Bat Cave, New Mexico, and La Perra Cave in Tamaulipas (northeastern Mexico), archaeologists discovered tiny corn cobs dating between 4,000 and 5,000 years ago. Famed archaeologist Richard MacNeish led the way in the 1970s in tracing the evolution of maize culture

► THE GENETIC PREDECESSOR OF MODERN CORN ON THE COB

Domestic corn's genesis remains a subject of controversy and conjecture. In particular, this controversy centers around what a number of scholars believe is the precursor to all forms of maize: a wild grass known as teosinte that can be found growing over much of Mesoamerica. Botanist George Beadle in 1981 postulated that teosinte evolved into a form of primitive corn via human selection. Beadle's theory states that the early forms of teosinte experienced a mutation that led to a genetic evolution that caused the grass to elongate, which protected and enclosed the kernels growing on it.

Through this change wild teosinte became easier to thresh, and as it progressed to a domestic form of maize it quickly spread as a crop in the Americas. According to the hypothesis supporting the notion that teosinte led to the genesis of corn, human beings needed and sought out predictable types of grass to harvest. Over time humans began to select more productive varieties whose seed was larger and more robust. Ancient Mesoamericans through natural experimentation saw to the planting of hardier and higher-yielding versions of the teosinte, which led to what today is modern maize.

—John S. Leiby

Teosinte, the genetic predecessor to modern corn. (Hugh Illitis/University of Wisconsin-Madison)

in the Americas. In the caves and rock shelters around Tehuacán (Mexican state of Puebla), MacNeish and his team of researchers determined that the natives inhabiting the area had lived primarily by means of hunting and trapping until about 9,000 years ago. Then these native peoples shifted to gathering wild plants and to the domestication of such plants as squashes and avocados between 9,000 and 7,000 years ago. MacNeish's findings showed that by 6,000 to 7,000 years ago the Tehuacán people were moving irrevocably toward agriculture, which explained the discoveries of 1948 indicating the ongoing evolution of maize culture that spread across the Americas after 3000 BCE.

As of today, no concrete evidence has been found of corn production in South America prior

to 3,500 years ago. However, scholars such as MacNeish and others suggest that South America experienced a similar evolution as that found near Tehuacán. Archaeologists, for instance, have found artifacts such as bottle gourds and lima beans near Chilca and Nazca (on the southern Peruvian coast) dating between 6,700 and 5,000 years ago, suggesting the nature of the movement of agriculture into South America. Available evidence generally indicates that agriculture remained a secondary activity in South America, and hence maize production there occurred much later and was not as extensive as in Mesoamerica.

Maize production nevertheless spread throughout the Americas over a protracted period of time. Maize was one of the earliest crops

to cross the Rio Grande after it had been cultivated in northern Mexico for some period of time. As a consequence of the climate, maize and bean yields were lower than those found in central Mexico, yet they were predictable. According to many scholars, it seems likely that southwestern Indians adopted maize cultivation because of rising populations and food shortages.

The variety of corn (low yielding) that first entered the Southwest was Chapalote. It probably appeared between 1500 and 1000 BCE and soon introgressed with the wild teosinte, which eventually resulted in a hybrid cob with more rows and kernels. However, a much more important type of maize known as Maiz de Ocho revolutionized corn production in the Southwest. It was robust with large kernels and required a short growing season and a temperate climate. Archaeologists have found Maiz de Ocho in southern New Mexico dating to about 1225 BCE. As with other maize forms, it spread widely and quickly in later centuries throughout the Southwest. By 300 BCE the spread of and evolution of hybrid maize from the south resulted in the development of a more sedentary way of life. This evolution led to the birth of the three great southwestern archaeological traditions: Hohokam, Mogollon, and Anasazi. These southwestern farmers persevered by adapting to their environment and harnessing scarce water resources through dams, floodwater irrigation, and other systems for distributing runoff. Planting techniques were also adapted over time to the desert environment to create sufficient harvests.

In eastern North America the indigenous peoples adopted the deliberate cultivation of food plants to supplement their supplies of food gained via hunting and gathering wild plants. This development nevertheless occurred much later in prehistory. It apparently came by way of the Southwest. Midwestern Indians grew the 12-row or Chapalote variety, and by the late 100s CE it was also known to southeastern Indians. The lower Mississippi, because of its floodplain, was the perfect setting for the cultivation of high-yield maize strains as well as beans. However, maize in these vicinities was grown chiefly as a supplementary foodstuff rather than as a staple as found in Middle America.

Mesoamerican Domesticates—Pumpkins, Squash, Avocado, and Amaranth

Tropical settings are anathema for the preservation of vegetable matter. The heavy rains and high humidity destroy the archaeological evidence of early plant (and animal) domestication. Yet new scientific techniques are pushing scholars' understanding of domestication back into prehistory. Accelerated Mass Spectrometry (AMS) dating of preserved rinds and seeds in addition to starch analysis on bowls and grinding stones are inexorably rewriting basic texts on domestication.

Early hunting and gathering groups probably domesticated squash and gourds about 10,000 years ago. These nomadic groups carried seeds and containers with them as they moved about on the landscape. Around 4,000 years ago, village life became important. Plant domestication enabled more people to settle for longer periods. At this point, villagers had accumulated significant knowledge of wild plant growth and used this knowledge to identify better food-producing varieties and crops that could be cared for near the village. Over time, some crops became more important than others. Maize (Maya: *nal*; *Zea mays*), beans (Maya: *bu'ul*; *Phaseolus* sp.), squash (Maya: *kum*; *Cucurbita* sp.), amaranth (*Amaranthus* spp.), and a host of fruits dominated the orchards and fields of Mesoamerica.

The earliest current evidence of domesticated pumpkins and squash (*Cucurbita* spp.) comes from the Guila Naquitz cave in Oaxaca, Mexico. Bruce Smith submitted samples of *Cucurbita pepo* for AMS dating. These were dated to 10,000 years before the present (BP). Pumpkins, squash, and other gourds were used for

food and were hollowed out for containers by archaic people. Some archaeologists believe that the earliest ceramics were modeled after gourd forms. Cucurbita species were often grown intermixed with maize in small fields or in gardens. Their nutritional value offsets the heavy carbohydrates of maize and provides variety to the diet.

Avocados (*Persea americana*) have been domesticated since 6,000 years BP and eaten in their wild state at least from 9,000 years BP. There are three main varieties of avocados: Mexican, Guatemalan, and West Indies. Avocado trees are often grown around the periphery of the garden plot in Mesoamerica or in their own orchards. Avocados prefer a Mediterranean climate and can grow up to 80 feet high. Fruiting occurs around year 8 from seedlings and continues for another 12 years.

Amaranth (*Amaranthus* spp.) is a psuedo-grain with a pedigree at least 6,000 years old. It was found throughout Mesoamerica and South America prior to contact and even extended into the temperate parts of North America. The tiny seeds of the plant can be eaten as popcorn or flakes or ground into flour. In North America, amaranth is frequently included in multigrain products such as bread, although in Mesoamerica and South America it is still grown for home consumption in family gardens. The Aztecs used amaranth in their religious ceremonies, which invoked the displeasure of the Spanish friars. In religious ceremonies, amaranth dough was used to create miniatures of deities, or sacred images. The dough idols were then passed around and eaten. In an effort to combat this practice (and others), amaranth sowing was discouraged by the priests.

Chile peppers (Maya: ik; *Capsicum frutescens*) are an overlooked part of the Mesoamerican diet. They were domesticated around 6,100 years BP, possibly in Ecuador. Their use, throughout Mesoamerica, was as a seasoning for food. Chiles were traded in the marketplace and consumed in a variety of dishes. We think of chile as a condiment, but it had other uses in ancient times. For example, the Aztecs would discipline their children by making them inhale the smoke from burning chiles.

Peruvian Fishing

The relative importance of marine resources in the ancient Peruvian diet is an often-argued issue in South American archaeology. Sometime between 3000 and 2500 BCE, more inland sites in Peru were abandoned for coastal sites. Some scholars have suggested that part of this change in settlement patterns may have been to allow

➤ SHELL MIDDENS AND THE SAMBAQUÍ TRADITION IN BRAZIL

Middens are ancient garbage heaps that are more than just garbage heaps for archaeologists. These refuse piles can provide important information on diet and subsistence since they provide clear evidence for materials that people used and discarded. In coastal regions of the Americas, shell middens are extremely common. These shell middens are usually composed almost exclusively of mollusk shells (although other materials can work their way into the piles).

In Brazil, these middens are called *sambaquí*, and this name is used to refer to a specific set of archaeological remains found on the Brazilian Coast, dating from 3000 to 1500 BCE. Some of the *sambaquí* associated with this tradition are flattened at the top. These flattened areas made for excellent living spaces during certain parts of the year since they were cooled down by the sea breezes and lay above the swarms of mosquitoes that appear seasonally. Stone tools shaped like fish and birds are frequently found in association with these middens.

—Kevin M. McGeough

for greater exploitation of marine resources. It has been suggested that these reliable fish resources allowed more complex settlements to emerge, eventually creating the first Peruvian states. Others have argued that marine resources were too unreliable to form the basis of subsistence and that Peruvians of this period lacked the capability to fully exploit this type of food source. Or, scholars argue that sites prior to 3000 BCE also relied on fishing, and thus there is no real change in subsistence strategy that can be dated to this period. These scholars would argue that the origins of complex civilization in Peru have no basis in fishing.

Whether or not fishing facilitated the development of complex civilization, there is significant evidence for fishing in Peru during this era. The remains of mollusks, fish, and sea mammals have been retrieved from a number of sites. The evidence is preserved as bones or shells or (as direct evidence that humans consumed these foods) in the intestinal remains of preserved bodies or in the coprolites at sites. Artifacts also attest to the importance of fishing: fishhooks, nets, net weights, and floats all would have been part of a fishing economy. Anthropologists who have studied the physical remains of ancient Peruvians have identified physical conditions typical of repetitive diving in cold water, the clearest evidence being inner ear bone growth.

Different types of marine creatures required different acquisition strategies. Fish were gathered much as they are today, using hooks or nets. Mollusks would have been collected by hand or raked from the shores (or close to the shores) of beaches. Mammals would have been hunted using similar techniques to those used on land: clubbing or spearing. There is not much archaeological evidence for the use of watercraft, but this possibility should not be discounted entirely.

■ Introduction: Pastoralism

People who choose to produce their food by farming are compelled to alter their environment. Pastoralists, instead of manipulating their environment, move to different environments, seeking out appropriate resources and ecological conditions. Pastoralism, then, represents a dramatically different strategy for coping with environmental constraints. This is a strategy that is still in wide use today and has been widespread since this period. By 1000 BCE, pastoralist economies had developed throughout Eurasia, Africa, the Near East, and the Americas. It is a strategy that is found on the margins

of habitable land and thus on the margins of settled agricultural society, even though agriculturalists and pastoralists interact frequently. Pastoralists survive in areas that are unsuitable for agriculture; what they require are large stretches of land where wild grasses grow in great enough abundance to provide for their large herds. These herds are the main source of a pastoralist's subsistence.

There are two main types of pastoralists. Nomadic pastoralists have no fixed homes. Rather, they follow fixed migratory routes, moving as the seasons change and as grazing resources

dwindle. Typically, nomadic pastoralists are fully self-sufficient, although they may trade with other nomadic groups or sedentary societies for luxury goods or supplementary supplies. While nomadism may bring to mind the idea of roaming without a fixed path, this is actually highly unusual. The movement of nomadic groups is highly purposeful and organized.

Transhumance pastoralists tend to move less far and return to the same regions seasonally. The typical transhumance strategy is to move the herd to the desert or steppe fringes when vegetation is at its peak. As temperatures rise and vegetation gets scorched, the pastoralist groups follow the retreating vegetation. Usually this means moving into highland areas (although this differs from region to region) where temperatures remain warmer in colder months and vegetation is found year-round. Sometimes transhumance simply involves moving back and forth between two regions so that not every member of the community follows the herd. Many of these transhumance pastoralists could be considered semisedentary and may have even practiced some small-scale agriculture. Likewise, many fully sedentary societies had smaller groups within that practiced transhumance, living with the larger group only seasonally.

Both types of pastoralism are well suited for temperature extremes. This is consistent with where archaeologists have identified pastoralist activities in the period from 4000 to 1000 BCE. In central Asia, for example, temperatures can range from -45° F (-43° C) in the winter to 120° F (49° C) in the summer. Desert temperatures, in the Sahara and Arabia, can also reach 120° F (49° C) in the day and yet still be below freezing in the winter. Even in the summer, night in the Saharan desert is very cold. Archaeologists, who typically start work very early, often have to wear warm jackets on cold desert mornings.

Pastoralist Society

The herd is the single most important aspect of a pastoralist subsistence economy and is crucial for the survival of the group. Herds supply almost everything that a pastoralist economy requires. Milk and dairy products are the most

important food supplies. Meat is also important, although the pastoralists must carefully strategize which animals to kill so that their herds do not die out. Clothing is made from the hides, wool, and hair of the herd animals. In central Asia and some parts of the Near East, tents are also made from the hides of herd animals. Almost all small tools are made from animal bone, as are art and pieces of jewelry. All of these products can be traded with other groups in order to gain materials that the group cannot produce themselves. So in a way, even goods that pastoralists have traded for are provided by the herd. In some societies, these animals also provide the primary means of transportation for the group. Without the herd, the people could not meet any of their primary needs.

There are a variety of different types of animals that are exploited by pastoralists. In Mesopotamia and Syria-Palestine, shepherd tribes who raised sheep and goats were most common in this period (and still are today). Some groups in this region also may have dwelt on the desert fringes supplementing their shepherding activities with the hunting of gazelle. In southern Mesopotamia there were also groups that raised cattle and water buffalo, although these were not nearly as common. African pastoralists were cattle herders during this period. The pastoralist groups of the central Asian steppes exploited multiple types of animals at once. During this period, these animals included sheep, goats, cattle (mostly water buffalo), and horses.

Pastoralists can live in groups of varying size. At the smallest are groups of 10 to 20 in which everyone is closely related. The largest groups are usually around 100 people, which may include a number of distinct lineages or where everyone claims descent from the same common ancestor. Almost every known pastoralist group is organized in a strict patrilineal manner; that is to say, descent is traced through the paternal (as opposed to maternal) line. There is no reason to doubt that this same patrilineal organization may have existed in this period, although there is little positive evidence to prove this. Based on modern anthropological studies, gender roles in pastoralist societies are fairly fixed. Men are directly responsible for the care of the herd; women are responsible for child rearing

and the production of goods (such as dairy products and clothing). Polygamy is relatively common within pastoralist societies, but it is difficult to determine how widespread this practice would have been in this period.

Pastoralist societies can be highly stratified, although this kind of stratification is not readily identifiable in the archaeological record. Scholars who study the years from 4000 to 1000 BCE are forced to base their conclusions on ethnographic analogy, although in some cases the archaeological excavations of pastoralist cemeteries have yielded proof of stratification. Often, individual status was based on herd size. Those individuals who controlled a large herd wielded more power within the community and thus had more access to trade goods and possibly wives in polygamous societies. Individuals with smaller herds could form debt or client relationships with these wealthier members, thereby increasing the status and influence of the wealthy individual within the group. Other high-status individuals within the pastoralist community may have been religious specialists, craft specialists (especially metalsmiths), elders, and perhaps successful warriors.

Typically, pastoralist groups are not portrayed in a favorable light by individuals living in sedentary communities. Egyptian and Mesopotamian accounts of pastoralists describe them as unlawful, hostile forces that cause problems for city dwellers. For this period, we do not have any texts that describe how pastoralists viewed settled people, but it is unlikely that ancient descriptions would have been flattering. However, these groups lived very much in tandem, and without a doubt the actual relationships were varied and complex.

One of the important motivating factors for any interactions between these groups would have been trade. Sedentary groups would have produced goods that could not be manufactured by pastoralists, the most noteworthy being metal tools and agricultural produce. Urban dwellers may have prized the meat, dairy products, hide products (especially skins), and exotic items that pastoralists could have provided. Neither pastoralists nor sedentary folk would have required the products produced by the other group but

may have wanted them nonetheless, facilitating contact between the two.

Hostilities between these two types of societies doubtless took many forms. If a pastoralist group was particularly powerful or skilled in fighting, a village may have paid tribute or given gifts to the group in order to not be attacked. If the city (or in some cases the state) was particularly powerful, it may have tried to tax the pastoralist groups, either for products or as military conscripts. Letters found in the palace at the Syrian city of Mari discuss the difficulties in getting pastoralist groups to submit to census taking.

Pastoralism in the Ancient Near East

The desert fringes of the Near East have long been home to pastoral groups keeping sheep and goats, generally in mixed herds in which sheep predominated. Goats produced milk and hair and tended to act as leaders of other animals within flocks, but they were chiefly a source of meat. Flocks varied in size, small farmers owning a few animals, whereas full-time pastoralists might manage several hundred. Although they frequently had permanent homes in one area, full-time pastoralists were generally transhumant, moving seasonally to obtain pasture for their flocks, during the winter staying in the steppe or desert fringes or on the wasteland between areas of cultivation and in summer moving to camp in settled areas where their flocks grazed on stubble and in fallow fields, leaving dung as fertilizer.

Grazing rights were negotiated and often established over long periods, both between different pastoral groups and between pastoralists and farmers. In the autumn the pastoralists returned to their own villages, where they often planted some crops. Some of the group, particularly the elderly and women with small children, might live in the villages year-round. Pastoralists also inhabited the Zagros and Taurus and the mountains of Lebanon, grazing their flocks in the rich upland pastures in the summer and returning to the foothills for the winter. As well as herding and cultivating, pastoralists engaged in trade and probably exploited wild plants and animals.

Pastoralism was a risky and fluid business in which substantial profits and drastic losses could occur. Shepherds whose flocks became too small might hire themselves out as herders or settle into a sedentary existence. Those whose flocks grew to considerable size might invest in land and settle down to manage it, hiring others to take care of their animals. Many rulers, such as the Assyrian king Shamshi-Adad and the Mari royal family, had nomad ancestors and relatives who lived in tents. Sedentism was also a response to climatic deterioration that reduced pasturage, as was raiding, especially in times of political instability. Frequently, however, farmers and pastoralists had a symbiotic relationship, exchanging grain for animals, wool, and other animal products.

Their mobility enabled pastoral groups to maintain large flocks of their own and to be employed as shepherds for the flocks of temples, kings, and wealthy landowners, taking the animals to pastures distant from the settled land where grazing was limited. For example, administrative texts in the town of Nuzi (near modern Kirkuk in Iraq) name 90 hereditary herders as part of the community, although they spent most of the year elsewhere.

Sheep were kept almost entirely for their wool, the main material for making textiles. The spring sheep shearing (actually plucking) was a major landmark in the agricultural year. Bones excavated from temple complexes show that most sacrificial animals were young kids and lambs; their meat was consumed by temple personnel, and their hides were processed for leather.

➤ MAKING A LIVING AS A SHEPHERD

Many surviving contracts are complex agreements between herder and animal owner in ancient Mesopotamia. The shepherd was usually given food and clothing for himself and pay for an assistant but took on considerable risks. One or two in every ten sheep would be accepted as a normal rate of annual loss; four in every five ewes were expected to produce a lamb, and every animal was expected to yield around two minas (slightly over two pounds) of wool. The shepherd generally kept the milk and a proportion of the wool, fixed in advance. Any lambs over the agreed number were also his. Large flocks were often dealt with by a herding contractor, who employed a group of shepherds, but the form of the contract was similar. The records of the great depot at Puzrish-Dagan, where animals paid in tribute were collected in Ur III times (2112–2004 BCE), give some idea of the huge numbers involved. Around 70,000 sheep and goats passed through it in the course of a year.

—Jane R. McIntosh

One important function of animals, particularly sheep and goats, was as a means of investment. Crop surpluses could be used to buy or feed additional animals. These would create interest in the form of lambs, kids, and wool and could be cashed in for grain or other commodities when the need arose. A specialist practice was fattening animals for the table on barley, particularly fat-tailed sheep, the fatty tail being a delicacy appreciated in the Near East to this day.

Herding in Southwest Kenya

Although scholars have assumed that agriculture in Kenya originated between 4000 BCE and 1000 CE, there is no strong evidence for any agricultural (or horticultural) activities. The subsistence practices of the people of this region and time are best thought of as a mixture of herding and hunting animals as well as gathering wild plants and marine fauna.

Shellfish were a particularly important source of food for the people of what is now called Kenya. Large shell middens (trash heaps) are typical of this era in this region. Basket traps were used to catch fish in Lake Victoria and the rivers of the region. Middens also tend to have many wild animals; a diverse variety of species were hunted, suggesting opportunistic local hunting as opposed to hunts planned with a long-term strategy in mind.

Perhaps the most easily identifiable group within Kenya at this time is the Elmenteitan Industry, situated mostly on the west side of the Rift Valley (in the high rainfall area). This group incorporated obsidian into their tool kits; they must have been part of a larger obsidian trade network, since many Elmenteitan sites are far from known deposits of obsidian. The Elmenteitan dead were cremated—unusual for Africa at this time—and at Njoro River Cave the dead were interred with food-processing equipment. These two traits (obsidian usage and cremation) make Elmenteitan sites stand out from other Kenyan cultures in this period. The Elmenteitan seemed to have practiced an equal mixture of herding and hunting; the animal bones recovered from sites usually show relatively equal proportions of wild and domesticated animals.

Saharan Pastoralism

By the beginning of the period between 1000 BCE and 300 CE, people living in the Saharan region of Africa had started practicing pastoralism alongside the exploitation of wild animal resources. At this time the Sahara was not the barren desert that we associate it with today. The area at the time had grasslands spread between small lakes located in the highland regions. Without a doubt, the human populations were concentrated near these water resources. This type of environment is well suited for a pastoralist economy. Pastoral species need large amounts of grazing land; the Saharan region provided a vast amount of space for these practices. Throughout this period, however, life in the Sahara became more and more difficult as environmental degradation set in.

The site of Uan Muhuggiag has some direct evidence of ancient pastoralist activities. The most important is a skull fragment of an ox, dated to 5000 BCE (1,000 years before this era). Dated to around 3400 BCE are numerous buried rock paintings of cattle. In associated contexts are grindstones, probably used for processing wild plants for consumption, suggesting that the people of Uan Muhuggiag did not rely solely on their cattle for subsistence.

Cave paintings of people with cattle, about 4000 BCE–2000 BCE at Tassili n' Ajjir, in the Sahara Desert of Algeria. (Patrick Gruban)

Arguably the most whimsical evidence for Saharan pastoralism in this period can be found at Tassili n' Ajjer in Algeria. Here numerous rock paintings tell us much about life in the Sahara. There are many images of cattle with humans. The paintings are so detailed that it is possible to distinguish different species of cattle (usually on the basis of the colors of their coats or the shape of their horns). People are depicted milking the cattle and riding the cattle, and some of the cattle may be depicted in pens. These paintings depicting cattle are usually considered part of the Bovidian Tradition; scholars use this term inconsistently, sometimes referring just to the style of rock art and other times referring to the people who painted this art. Later paintings from Tassili n' Ajjer show horses and camels as well, but these paintings date to the subsequent period.

From about 4500–3300 BCE, the Ténéréan Industry ran from northern Niger to northern Chad. By the term “industry,” archaeologists mean a set of shared technological and economic traits that are found over a distinct geographic region. This industry includes stone tools (such as knives and microliths) as well as grinding stones, significantly more sophisticated tools than are typically found in association with Bovidian sites. The Ténéréan people hunted wild animals and gathered wild plants. However, ox bones from the site of Adrar Bous prove that these nomadic people also raised domesticated animals.

In central Niger during this time period, the people of the Tilemsi Valley were also cattle herders. The first cattle herders appear in this region around 3300 BCE. By 2000 BCE they moved into the southern parts of the valley (including the Karkarichinkat sites), leaving behind (for modern archaeologists to find) cattle bones, clay figurines of cattle, and tools for hunting and fishing.

➤ GIRAFFE HERDERS?

As people began domesticating animals and employing them in pastoralist practices, it is likely that there were a few failed experiments. People probably attempted to herd antelope rather than just hunting them. In the Jebel Uweinat in Libya, there are numerous pieces of rock art depicting humans interacting with giraffes. A few of the images show what must be giraffes tethered to a spike set into the ground. Others show humans leading the giraffes on relatively long leashes. Unfortunately this rock art cannot be dated, so we are left to wonder who was catching giraffes in Libya, and when.

Nomadic Groups in Egypt, 4000–1000 BCE

Egypt’s remarkable geography created a land of major urbanized oasis surrounded by deserts incapable of supporting urban lifestyles. The Egyptians often found themselves in direct contact with groups of nomadic peoples whose seemingly chaotic lifestyle did not mesh well with the Egyptian concept of *maat*. *Maat* is a term that does not bear English translation well. The closest basic meaning would be “order.” Maintaining this cosmically ordained order was one of the key roles of the Egyptian pharaoh. As such, regular military action against these nomadic groups in order to reestablish *maat* was of key importance. In some cases, this sort of belligerent

contact with these groups led to some surprising results within Egypt proper.

Among the earliest evidence for contact with foreign groups comes from the eastern borders of ancient Egypt with the world of the Sinai pastoral nomads. As early as the Chalcolithic period of the Levant (ca. 4500–3500 BCE) and the Middle Predynastic (ca. 4400–3000 BCE) and Early Dynastic periods of Egypt (ca. 3000–2686 BCE), there is evidence of trade between these two groups and evidence for Egyptian attempts to establish a degree of permanent control over that region in the form of way stations and encampments along communication routes. Friendly trade as well as military campaigning by the Egyptians in the regions goes on throughout the Old and Middle Kingdoms. At Beni Hasan there is a famous series of paintings in the tomb of the local nomarch, Khnumhotep, showing his proud hosting of Abisha, an Asiatic caravan leader and tribal chieftain.

With the marginality of the Sinai, changes in climate often meant that locals were forced to migrate either north into the Canaanite world or west into Egypt. Such a model is seen in the narratives of the patriarchs in the Old Testament, where when famine hits they flee to Egypt. Eventually these Asiatics, or Aamu, become a significant enough threat to Egypt that a chain of fortifications called the Wall of the Ruler is built during the Middle Kingdom to limit access to the delta. The Egyptians, however, continue to impose their form of order on the Levant during the period and regularly raid the Sinai and further north into urban Canaan in order to take captives, who were forced into servitude in Egyptian homes. The large base of ethnically Levantine people living in the delta by the end of the Middle Kingdom likely made it much easier for the Hyksos to take over Egypt from their bases in coastal Canaan and begin the First Intermediate period, Egypt's first experience with foreign rule.

To the south the Egyptians faced the people of present-day Sudan. These people, known en masse to the Egyptians as Nehsy, or Nubians, included various groups, many of whom were pastoral nomads dwelling in caves. They often supplemented their lives by raiding Egyptian caravans heading south. Again, these people were

considered a sufficient threat to the Egyptian view of order, and thus regular campaigns were conducted in Nubia by the Egyptians, and massive fortifications were built at places such as Semna and Buhen to protect Egypt's southern frontier. The Egyptians were, however, so impressed with the military abilities of at least one of the Nubian subgroups, the Medjay, that they recruited many of them into the Egyptian Army as mercenaries and, more importantly, as the core of the Egyptian national police force.

To the west in what is today Libya lived a group of nomadic peoples called the Tjemhu and Tjehnyu. These fair-skinned red-haired people lived around the oases in the deserts west of the Nile. These groups were in conflict with the Egyptians as early as the reign of Narmer, who united Upper and Lower Egypt. By the time of the New Kingdom, some of the subgroups among the Libyans had gained sufficient power and wealth to hire mercenaries from the Aegean world and become a significant threat to the Egyptians. Again, much like they had with the Asiatics who came to dominate them as the Fifteenth Dynasty and the Sixteenth Dynasty, within a few centuries these same Libyans would come to be Egypt's next foreign rulers as the kings of the Twenty-Second Dynasty and the Twenty-Third Dynasty.

The Negev and the Sinai

The Negev and Sinai deserts in antiquity were home to groups of pastoral nomads who herded sheep and goats and, as conditions permitted, tended to crops planted along the beds of seasonal streams (wadis). Even today, some local

Bedouin engage in similar activities. Unlike the agriculturally rich coastal plain and lowlands of Israel or the Judean Highlands, the Negev and Sinai deserts are semiarid regions. Throughout much of antiquity these regions were home to specialized hunter-gatherers and, after the advent of domesticated animals and crops, to seminomadic pastoralists who may have formed the core of the urbanized population of the Early Bronze Age.

While the earliest agriculture and stockbreeding was occurring in the rest of the Levant, the Negev and Sinai were still dominated by specialized hunter-gatherers who traded with the early Pre-Pottery Neolithic (ca. 8500–7500 BCE) peoples to their north. Part of this trade must have included early domesticated sheep and goat, which were subsequently introduced into more marginal regions. The Chalcolithic period (4300–3300 BCE) marks the high point for pastoralism in the Negev. During this period the main center of activity in Israel was in the vicinity of the Wadi Beersheva and Wadi Besor in the northern Negev. This region was essentially uninhabited during the preceding period but became home to sites as large as 10–20 acres as well as many very small seasonal encampments during the Chalcolithic period. It is thought by some that these larger centers were home to chieftains and to tribal religious and burial centers. This is based to some degree on cemeteries where there was evidence for some of the tombs being much larger than others, possibly suggesting a more hierarchical than egalitarian society.

It is possible that during this period rainfall was considerably higher than today. Even with more rain, though, this region is still somewhat marginal and requires a lifestyle that is mobile and keyed to taking advantage of seasonal resources. It is likely that crops (probably barley, wheat, lentils, and vetch) were grown along wadi beds to take advantage of winter flooding and that when not sowing or harvesting the people of the Beersheva cultures were herding sheep and goats. Most of the smaller sites show regular abandonments, suggesting that they were indeed seasonal encampments rather than permanent settlements.

Contemporaneous with these sites in the Negev are numerous small sites in the Sinai. Among

➤ DIET IN THE NEGEV AND SINAI

Woman carrying a churn over her head and a ram with cornets on its back. From Gilat in the Negev, Chalcolithic Period. (Erich Lessing/Art Resource, NY)

Ninety percent of the animals identified from these campsites are the remains of domesticated sheep and goats. The virtual lack of any sort of arrowhead among the lithic toolkit of the Chalcolithic cultures suggests that virtually no hunting was being conducted. The consistent use of images of churns, cornets (horn-shaped pots thought to have been used for holding milk), and dairy animals (sheep, goats, and cows) in the imagery found in their religious centers suggests that the Chalcolithic people had an economy focused on the use of secondary products such as milk, cheese, yogurt, and butter.

—David R. Lipovitch

these sites were *nawamis* (a type of clustered circular stone burial structure with a central pillar) and numerous pit dwellings. Sites along the Sinai coast were likely the seasonal homes of pastoralists planting crops there in much the same manner as do modern Bedouin of the Sinai.

In the subsequent Early Bronze Age, the beginnings of urbanization are seen, and the center of population moves north away from the Negev. While the region depopulates to some degree, there is still continuity with the establishment of unfortified villages in the region. The nawamis and related occupational sites found in the Chalcolithic Sinai continue through the Early Bronze Age I (3300–3050 BCE). It is likely that some of the Negev sites acted as intermediaries between the more urban centers of the north and the pastoral nomads of the Sinai. These Sinai nomads may have also acted as intermediaries between the Levant and the people of Predynastic and Early Dynastic Egypt. In the period immediately following, the Early Bronze Age II (ca. 3050 BCE), there is evidence for a significant population in the Sinai. Surveys in that region identified 50 sites clustered along the wadi systems. These sites consisted of central courtyards surrounded by a mixture of rounded and rectangular dwelling rooms. The rectangular rooms are typical of the sort of structures found in the north at urban Early Bronze Age sites, while the round ones are characteristic of local Sinai structures dating as far back as the Neolithic period. Ceramics found at the sites show clear links between these Sinai people and the populations of Arad in the northern Negev. It is likely that these sites represent a mix of local Sinai pastoralists living alongside people mining the nearby copper sources needed by the urban populations in the north.

At the end of the Early Bronze Age II there is an almost complete depopulation of the Sinai and Negev. Similarly, in the more urbanized parts of the Levant there is a centralization of people in large well-fortified urban centers. It is unclear why this occurs, but it is likely due to a combination of factors including interurban warfare and a drying of the local climate. At the end of the Early Bronze Age III there is a further collapse among the urban centers of the Levant. With the advent of the Early Bronze Age IV/Middle Bronze Age I, all urban centers west of the Jordan disappear, and only a handful of centers continue to exist east of the Jordan River. This leads to a second rise of pastoral nomadism as the dominant lifeway in the Levant.

Many hundreds of small settlements and handfuls of 5- to 12-acre villages appear alongside vast communal cemeteries and tumuli fields throughout the Levant. The largest of the centers had populations of fewer than 100 people. In the Negev alone, more than 500 such sites have been identified. In the Sinai, there is evidence for more than 200 ephemeral campsites along the coast. Unlike the Early Bronze Age II, however, there are no sites in the more marginal Sinai highlands. Typical sites of this period consist of rounded single-room structures with a central pillar surrounded by animal pens.

With the beginning of the Middle Bronze Age IIA and the reurbanization of the Levant, there is a near complete disappearance of sites from the Negev and Sinai. While over time pastoral nomads such as present-day Bedouin do indeed return to the Negev and Sinai deserts, such pastoral nomadism never again becomes the dominant lifeway of the Levant and is limited to small populations taking advantage of the limited resources of a marginal area.

The Andronovo Culture and the Timber Grave Cultures

The geography of central Asia is well suited to a pastoralist lifestyle since much of it can be char-

acterized as semidesert or steppe. In the period between 4000 and 1000 BCE, one of the best understood of these central Asian nomadic groups is the Andronovo culture. The name comes from the site of Andronovo, which was first excavated in 1914. The use of the term “culture” here may be misleading. It is best to think of the Andronovo as a group of several individual cultures with a number of shared features; there is no evidence that they were ever unified politically. The Timber-grave culture is named after the type of graves that are typical of the group but are also known as the Srubna culture, based on the Russian word *srub* (“timber”).

The Andronovo culture was quite widespread; remains have been found throughout western Siberia, Russia, and Kazakhstan dating from 2300 BCE to about 1000 BCE. The Timber-grave culture was located directly to the west of the Andronovo culture and extended as far west as the Black Sea. The two groups were roughly contemporaneous, and most scholars assume that there was some relationship between these two groups. However, the two cultures have different burial practices, which may indicate quite different belief systems.

Both cultures are interesting examples of settled pastoralists. These people do not seem to have been nomads. Instead, they lived in small villages in houses built of timber. However, it is important to recognize that some members of the community may have lived as seminomads and during certain parts of the year may have lived apart from the community along with their herds.

Some of the villagers engaged in copper mining, and long-distance trade in mineral resources may have been an important component of economic life. The horse had likely been domesticated in this region around 4000 BCE or perhaps slightly earlier. Initially, horses were probably bred for their meat, and horsemeat was probably an important component of the Andronovo and Timber-grave diet. Horses, however, came to play an extremely important role in transportation at this time. Burials often included horses

➤ YURTS

Nomadic groups who lived in this region of the world lived in temporary tent-like structures called yurts. These were structures that were made out of hide and wood and were generally circular in shape. Hide would have been readily available to the pastoralists, but wood was not as common in the steppe regions and was probably acquired through trade. These tents could be easily set up and taken apart, and they were lightweight and easy to transport, perfect homes for people on the move. These types of structures are still used in Mongolia today and are viewed as a nationalist symbol in various parts of central Asia.

—Kevin M. McGeough

and chariots, and the first evidence for the spoke-wheeled chariot is associated with these cultures.

Other animals besides horses were part of the pastoral economy. Cattle were probably the most important subsistence animal after the horse. Goats and sheep were also herded but not to the same extent. Dairy products, hides, and meat would have been the major types of products derived from this pastoral lifestyle, and these would have been traded with nearby agricultural communities (such as the Bactria-Margiana Archaeological Complex) for cereals, such as wheat and barley.

■ Introduction: The Americas—Many Ecozones, Many Ecostrategies

Broad geographical patterns are visible in the distribution of archaeological remains of prehistoric American peoples. These patterns are thought to be the result of shared cultural practices that prehistoric American peoples utilized to solve problems they faced in adapting to the various ecologies of the Americas. In each major continental region these shared cultural solutions (ecostrategies) have been identified and clearly delineated. North America under this delineation is broken up into ten general areas based on the ecology and ecostrategies pursued in each area by prehistoric peoples: Arctic, Subarctic, Northwest Coast, California, Plateau, Great Basin, Southwest, Plains, Northeast, and Southeast. For example, evidence indicates that prehistoric peoples of the Great Basin practiced a similar ecostrategy throughout the area, one largely dictated by the basin and range ecology of the area. Similarly, prehistoric peoples of the Southeast practiced a similar ecostrategy based on hunting and gathering wild foods with an increasing emphasis on the gathering and gardening of seed-bearing plants over time.

To the south, Central America is generally split into four primary areas, each of which required unique ecostrategies: the Atlantic Lowlands, the Central Highlands, the Pacific Lowlands, and present-day Mexico, which is split further into several subareas.

Like the North American continent, the South American continent is extraordinarily diverse in the range of ecozones it prehistorically offered. The most outstanding features of South America are the Andes Mountains and the large tropical river systems of the Orinoco, Amazon, and La Plata. These environmental and geographic features prehistorically created several ecozones that each required their own unique ecostrategy. These ecozones are generally broken up into 15 general areas: Caribbean Plains, Pacific Plains, Orinoco Plains, Andes Mountains, Sabana de Bogota, Altiplano, Guiana Highlands, Amazon Basin, Llanos de Mojos, Mato Grosso,

Gran Chaco, Brazilian Highlands, La Plata Basin, Pampas, and the Patagonian Deserts. For example, the ecostrategies pursued on the Pacific Plains focused primarily on marine resources and were very different than those utilized in the Gran Chaco, which required a more varied ecostrategy due to the seasonal nature of the area's ecozone.

Bison in the Great Plains

American Bison adapted well to their ecological niche and provided valuable resources that could be profitably exploited by human predators. The contemporary species of American bison (*Bison bison*) appeared in the Great Plains around 5,000 years before the present (BP) as a relatively smaller species than that previously found in the Americas. Before this time, several other species of bison existed in the North American plains as part of a Pleistocene megafauna complex: *B. latifrons*, *B. priscus*, and *B. antiquus*. All of these species of bison were descended from prehistoric Eurasian populations. By the Middle Holocene, however, only *B. bison* remained extant, primarily as a result of climatic and environmental changes that took place at the end of the Pleistocene and the beginning of the Holocene as well as possible population pressure from early American Indian groups.

The physical and social evolution of American bison fitted it to the newly emerged Holocene Great Plains ecosystem with its climatic seasonality and cyclicism and, to a lesser degree, woodland habitats elsewhere in North America.

The strongly seasonal breeding and birth patterns of American bison proved well suited to the seasonality of the newly emerged Great Plains environment. Similarly, the low stability of bison group membership helped to adapt the species to the low patchiness and high cyclicism of food

abundance on the Great Plains. Flexibility in birth-site selection and the determinants of dominance status among cows helped bison adapt to the range of habitats and to the fluctuations in carrying capacity of the Great Plains ecosystem. These adaptive traits allowed bison to become

the dominant ungulate fauna (animals with hooves) in the Great Plains ecosystem during the Holocene, and these characteristics allowed Middle Holocene peoples to base a large portion of their lifeway pattern around bison and bison-related resources.

Across the Great Plains the climate varied considerably during the Middle Holocene, but overall it was marked by a north–south gradient of increasingly warmer and drier conditions with a reduction in effective moisture, surface water, and resource abundance and an increase in resource patchiness, sediment weathering, erosion, and aeolian activity. These factors resulted in pronounced drought conditions in the southern Great Plains and in either resource abundance or patchiness in the northern Great Plains, factors that influenced how Middle Holocene peoples inhabited the region. In the southern Great Plains where drought was most severe, surface and groundwater sources dried, and bison populations became diminished, prompting substantial adaptive changes by Middle Holocene peoples of the area, including local abandonment, well digging to tap underground water, and a widening of the diet breadth to incorporate higher-cost, lower-return seed and plant resources. To the north, where drought conditions were not as severe, Middle Holocene sites also evidence an increase in diet breadth and perhaps changes in settlement mobility, although the evidence is not as pronounced as in the south.

Bonebed 2 at Bonfire Shelter, Texas, originally excavated in the 1960s and dated to the Early Holocene, is one of the earliest bison-processing sites known in the Great Plains. Numerous other kill and processing sites have been found throughout the Great Plains that date to the Middle Holocene, and some contain evidence of continued use by prehistoric peoples from the beginning of the Early Holocene through the end of the Middle Holocene. The abundance of these types of sites, along with their chronology, indicate that Middle Holocene peoples of the Great Plains relied on bison for a substantial portion of their subsistence and economic resources despite specific regional climatic conditions. For example, archaeological evidence from the Powder River Basin in Wyoming has revealed several thousand sites from the Middle Holocene age

along with one stratified site that dates back to the Early Holocene. This site is a remnant of a much larger one that contains cultural levels including Clovis, Folsom, Agate Basin–Hell Gap, Alberta–Cody, and small Middle Holocene lithics, respectively. The site location and the taphonomics of the bone bed suggest that its use was primarily associated with the procurement of bison throughout the Middle Holocene.

During the Middle Holocene, people hunted bison by a number of means, as evidenced by the variety of lithic assemblages and processing tools recovered throughout the Great Plains, but the use of bison jumps appears to have been a common technique throughout the Great Plains. The Hawken site, located in northeastern Wyoming and dating to around 6,500 years BP, for example, is a steep-sided arroyo into which small groups of bison were driven and slaughtered. The projectile points recovered from the site are of a side-notched tradition, and the butchering tools are similar to those found in most bison kill sites dating from the Early Holocene to the end of the Middle Holocene. This evidence suggested to Frison and colleagues that bison procurement methods and reliance on bison changed little during the Middle Holocene despite regionally specific environmental conditions.

The importance of bison to Middle Holocene peoples of the Great Plains went beyond simple subsistence reliance. Evidence indicates that only the heaviest nonmeaty bones were left at the kill site, while the bones rich in marrow were chopped up for marrow extraction. Likewise, although the evidence is scant, it is generally assumed that perishable items from the bison, such as skin and fur, were also utilized by Middle Holocene peoples for a variety of purposes.

Head-Smashed-In Buffalo Jump

The site of Head-Smashed-In Buffalo Jump is located where the foothills of the Rocky Mountains and the Great Plains meet near Fort Macleod, Alberta, Canada. Head-Smashed-In is the site of one of the oldest and best-preserved buffalo jumps known to archaeologists. The aboriginal population of the plains used the precipice as a means to hunt bison by driving them over the edge to their deaths. At the bottom of the buffalo jump was an area where the hunters camped and carcasses were processed. Several similar jump sites are located nearby to take advantage of the terrain and the behavior of the bison.

The site was first archaeologically investigated by Junius Bird of the American Museum of Natural History in 1938. Since then, three major archaeological projects have continued the investigations of the complex. The Head-Smashed-In site is composed of a gathering basin, drive lanes, the cliff kill site, and the processing area below.

West of the cliff lies a large basin that was a natural grazing area for bison. From this, lines of stone cairns were built to direct the bison to the cliff. These drive lines extend for more than 8.6 miles (14 kilometers) into the gathering basin. It is unclear whether these cairns were simply piles of stone or whether in antiquity they may have supported brush to hide the hunters from the view of the bison.

To start the hunt, young men would lure the herd into the drive by mimicking the bleating of a lost calf. As the bison moved into the drive lanes, the hunters would circle behind and up-

View of the Head-Smashed-In Buffalo Jump site in Alberta, Canada. (Ken Thomas)

wind of the herd and scare the animals into stampeding toward the cliff edge. At the cliff edge the lead animals might try to stop, but the weight of the herd behind would have forced them over the cliff. Immediately below the kill site are stratified deposits 36 feet (11 meters) deep that contain evidence of use going back more than 5,700 years. Artifacts found in the kill site include bison bone, stone tools, and projectile points. The oldest evidence of humans at Head-Smashed-In are two Scottsbluff spear points. These projectile points date back 9,000 years. Near the kill site itself was a flat area where the hunters camped when processing the carcasses. Here the meat was sliced into thin strips and hung to dry in the sun. The large bones of the bison were smashed to extract their marrow. Numerous boiling pits and smashed bone indicate that the remaining bone was boiled down to render its grease. Artifacts found in this area include tools used in processing the carcasses such as scrapers, knives, and choppers. Also in this area were found vast amounts of fire-cracked rocks used in the boiling pits. In 1981, the United Nations Educational, Scientific and Cultural Organization (UNESCO) declared Head-Smashed-In Buffalo Jump a World Heritage Site.

Marine Mammal Hunting in the Arctic, 4000–1000 BCE

The global climate changes at the end of the Pleistocene and beginning of the Holocene (about 9550 BCE) led to the extinction of the typical representatives of Late Pleistocene megafauna in the arctic. By the Middle Holocene (about 3500 BCE), new ecosystems had become established, and arctic peoples changed their lifeways to adapt to the available resources. Those peoples living along the coast had to adapt different subsistence strategies (practices to gain food, clothing, and shelter) than those inhabiting the interior, and the archaeological tool kits of both groups reflect this. Interior peoples oriented their lifeway patterns around the caribou and other faunal resources, while those on the coasts focused much of their subsistence lifeway patterns on marine resources. The major components of the arctic marine fauna during this period were made up of marine mammals: whales, walrus (*Odobenus rosmarus*), and seals. The two major species of seals that occurred in the arctic at the time were the ringed seal (*Phoca hispida*) and the bearded seal (*Erignathus barbatus*).

Archaeological evidence indicates that notch-point and lanceolate-point lithics, along with microblades, made up the primary items of these peoples' tool kits, which has come to be known as the Arctic Small Tool (AST) tradition. The AST tradition includes the archaeologically distinct assemblages from a variety of sites in Alaska, Greenland, eastern Canada, Manitoba, and the Yukon. These people focused their activities around the coasts, although evidence indicates that they maintained some interest in interior subsistence pursuits, and in some locations marine mammal resources provided enough of a consistent and substantial resource to support sizable settlements. Since there is considerable

variability in the tools that are included in the AST tradition, it is presumed that the makers of these tools had contact with one another but adapted their manufacture to their own particular preferences.

The overall importance of marine mammal hunting for Middle Holocene arctic peoples is further supported by the location of settlements. For example, archaeological evidence from the northeast coast of Devon Island, Northwest Territories, indicates that there is a significant positive correlation between locales and access to marine mammal resources, with high site densities found where access to these resources was readily available and low site densities located near sedge meadow or freshwater resources. These site distributions are most likely the result of marine mammal ecology in that during winter months, seals are found in open water or along sea ice fissures, while during spring, summer, and fall months, seals stay closer to shore or the ice floe edge. The Saatut site, located on the northern coast of Baffin Island, for example, appears to have been inhabited mostly in the summer and fall as a fishing and seal-hunting camp.

The seacoast locations of settlements, along with the presence of harpoon heads and numerous other artifacts of seal and walrus bone and ivory, attest to the importance of seal and walrus in the subsistence economy of arctic peoples during the Middle Holocene. Evidence for beluga (*Delphinapterus leucas*) and narwhal (*Monodon monoceros*) hunting, on the other hand, is less conclusive but sufficient to suggest at least occasional exploitation. However, whaling appears to have been greater in some areas of the arctic than in others. Evidence indicates that whaling accounted for approximately 12 percent of dietary intake of the peoples of this region, with a high proportion of other marine mammals also found to be part of these peoples' subsistence regime.

Although reliance on marine mammals remained constant over the Middle Holocene, the implements used to take marine mammals did not. The harpoon heads for sea-mammal hunting appear to follow a stylistic progression through Pre-Dorset time, with the earliest versions known coming from Igloodik, northwestern Foxe Basin, Mittimatalik, northeastern Baffin Island, and Port

Refuge on Dundas Island. These harpoon heads have a single line hole, are self-bladed with single or bilateral barbs, and have open sockets. Subsequent Dorset period evidence indicates that harpoon heads shifted from open sockets to closed sockets as the subsistence economy continued to be dominated by seals of several species. Walrus bones appear in middens (large garbage heaps) in relationship to access to better hunting sites, while narwhal and beluga hunting appears to have lessened in importance, though there is some evidence indicating active hunting of the baleen whale.

Although peoples' cultural practices along the coast during this time were focused on marine mammals, evidence indicates that there was a marked difference between kill sites and residential sites. For example, archaeological site distributions indicate that ringed seals were usually transported whole from kill sites to residential sites on the eastern Canadian arctic coast and Greenland. Some have argued that this indicates that intra- and interhousehold activities such as food-sharing mechanisms may have played a more significant role in conditioning butchering variability and assemblage composition than transportation from hunting locations.

Following the Caribou, 4000–1000 BCE

As climate changed in North America, the inhabitants of the more northerly regions adopted new strategies to cope with new temperatures, new environmental conditions, and new food resources. One solution to these climatic changes was to increase reliance on caribou as a source of subsistence in the region.

Changes in arctic and subarctic flora and fauna during the Late to Middle Holocene (fully evident by about 3500 BCE) reflected the influence of the changing climate induced by the retreating ice sheets, orbitally driven seasonal insolation patterns (patterns of solar radiation), increasing carbon dioxide concentrations, and relatively rapid internal variations. At regional scales, these climate changes resulted in ecosystem variability that impacted arctic peoples and their access to resources. During the Late Pleistocene, arctic peoples used fluted points (spearheads with a groove carved into them that would allow them to be fit snugly into a shaft) to hunt large mammals, including caribou (*Rangifer tarandus*) that inhabited environments across the arctic, from Alaska to the coast of Labrador and parts of Greenland. Rapid regional warming at the beginning of the Early Holocene and continuing into the Middle Holocene coincided with the abandonment of fluting technology and the development of other point styles and hunting technologies. By the time of the Middle Holocene (3500 BCE), evidence indicates that all of arctic Canada, Greenland, and Alaska were inhabited by peoples who utilized a variety of notched, stemmed, and lanceolate (spear-shaped) projectile points. This tool kit is characteristic of peoples who practiced hunting and gathering lifeways that were dependent upon maintaining access to key faunal resources. Specifically, evidence indicates that caribou were an important resource not only in the diet of these peoples but also in other aspects of their lifeway pattern as they followed the caribou herds between their winter breeding grounds and their summer feeding grounds.

Evidence indicates that during the fall and winter months arctic peoples followed the caribou from tundra areas to forested taiga regions or exposed ridges and hillside slopes, while during spring and summer months they followed the caribou into lower-lying resource-rich areas. Prior to the development of this subsistence pattern, archaeological evidence indicates that arctic peoples initially followed the caribou and other faunal resource northward from lower latitudes as a response to the climatic warming during the Middle Holocene. However, there is also limited evidence of continued occupation by people in some regions of the arctic from the early Holocene through the Middle Holocene. Despite this possible northward movement of peoples, and perhaps as a result, the variations found in lithic point styles associated with caribou are substantial, both in the form of the implements used and in the presence or absence of microblades in the assemblages. This heterogeneity in point styles has been used by some researchers to define specific prehistoric cultural groups.

Regardless of the cultural affiliation of these prehistoric hunting and gathering peoples, archaeological evidence indicates that the peoples of the Middle Holocene followed the caribou herds in their seasonal rounds between winter breeding grounds and summer feeding grounds. In this lifeway pursuit these people appear to have been highly skilled at hunting caribou with bows, arrows, and lances of both thrusting and throwing types. Evidence indicates that the bows were small, composite, and sharply recurved, while arrows had long, slender bone or antler foreshafts that ended either in blunt tips or in gouged-out beds for a stone tip. Help in hunting caribou and other large mammals was possibly further aided by large domesticated dogs. By the end of the Middle Holocene (around 2000 BCE), however, evidence indicates that the bow and arrow was dropped from these people's tool kit, as was the use of dogs.

Overall, the common weapon for taking caribou appears to have been the lance with a bone foreshaft and open-socked head. Pre-Dorset, Independence I, Saqqaq, and Arctic Small Tool cultures (all distinct archaeologically defined cultures) were associated with this technology,

although there was a wide diversity of specific traits unique to each of these cultures. The lance allowed large quantities of caribou to be taken, such as by driving them into lakes where they could be speared, as evidenced by the high concentration of caribou bones found in lakeshore sites. Similarly, the lance and the bow and arrow were ideal weapons for the taking of caribou at key geographic locations along the well-defined caribou migration routes, such as mountain passes and drainage systems.

Not only was the tool kit of these peoples geared toward hunting caribou, but so were other aspects of their lifeway. For example, evidence from Nain, located on the central Labrador coast, indicates that people used a variety of shelters that could be easily constructed and transported as the caribou moved from their winter grounds to their summer grounds. Settlement types included semisubterranean shelters or stone-lined tents that were probably caribou-skin-covered hemispherical tents made of flexible willow frames with unlined fireplaces located in the middle of the floors. Furthermore, these peoples' religious, ceremonial, and spiritual lives also revolved around the caribou to some extent.

Food Management on the Northwest Coast, 4000–1000 BCE

The Northwest Coast of North America, stretching from the Copper River in Alaska south to the present-day Oregon and California border, was one of the first areas in the Americas to be peopled. The area also possibly functioned as a corridor in the initial peopling of the Americas. Because people had lived and subsisted along the Northwest Coast since the first settlement of the Americas, the people of this region developed a complex relationship with the ecology and resources there. There is strong empirical evidence that by the Middle Holocene (5500 BP) the peoples of the Northwest Coast were actively, and inactively, managing the subsistence resources of their local environment.

The recovery of seal and sea lion remains from archaeological sites, along with shell midden remains on northern coastal islands of the Northwest Coast, indicates that the peoples of the region used seaworthy canoes and sophisticated technology in their subsistence pursuits. This technology allowed prehistoric Northwest Coast peoples to exploit seals and sea lions along the coasts of California and Oregon. Originally it was argued that these peoples exploited these resources to the point of destruction. However, recent evidence argues that these peoples managed this resource primarily through the incorporation of other marine mammal resources of the region. Farther north along the coast of present-day British Columbia, seaworthy canoes and sophisticated technologies allowed Northwest Coast peoples to exploit large quantities of shellfish, as evidenced by large shell middens on the Queen Charlotte Islands. Archaeological evidence indicates that Middle Holocene peoples of the Northwest Coast did not overexploit this resource.

Part of the food-managing strategy of Northwest Coast peoples during the Middle Holocene was in the shifting of sites for food harvesting and processing. Shell midden sites from the central coast of British Columbia, for example, suggest that resource exploitation in this region was strongly linked to the gradual long-term decline in relative sea levels during the Middle Holocene. Thus, Northwest Coast peoples must have successfully managed this resource over a long period of time.

Another food-management strategy used during this period is the continued long-term reliance on salmon (*Oncorhynchus*). This evidence indicates that salmon exploitation took place at a manageable level, allowing for continued yield. For example, ancient DNA identification of salmon remains from the site of Namu, a prehistoric permanent village on the central coast of British Columbia, shows use of a variety of salmon species with an emphasis on pink salmon during the Middle Holocene. These results support arguments that salmon exploitation took place at a manageable level by peoples of the Northwest Coast during the Middle Holocene. In fact, evidence from throughout the Northwest Coast indicates that sockeye (*O. nerka*), pink (*O. gorbuscha*), coho (*O. kisutch*), chum (*O. keta*), and chinook (*O. tshawytscha*) varieties of salmon were harvested at sustainable levels from the Middle Holocene (2500 BCE) to the present.

Further evidence for such a conclusion comes from the Fraser River and its tributaries, where the people of the Middle Holocene appear to have actively managed the salmon population in order to support the relatively large population of peoples living in the area at the time. Along the Fraser River in the Lillooet region of British Columbia, villages ranged from 500 to 1,000 individuals toward the end of the Middle Holocene. Salmon heavily dominated the subsistence economy of these groups, who appear to have effectively managed this food resource for several thousand years in order to maintain such a population density. Toward the end of the Middle Holocene (about 2000 BCE), catastrophic landslides along with persistent forest fires and summer droughts altered the local ecosystem enough to have caused this resource

to collapse, which was followed by the subsequent collapse of these population groups.

Farther south along the coast of Washington at the Ozette site, evidence indicates that a wide range of both marine and land resources were manageably exploited. Seal, whale, halibut, lingcod, salmon, and shellfish were all taken by Middle Holocene peoples who occupied this site throughout the year. Not only were marine resources actively managed by Northwest Coast peoples during the Middle Holocene, but so were land faunal resources such as blacktail deer (*Odocoileus hemionus*), the Dall sheep (*Ovis dalli*), and breeding colonies of seabirds that seasonally provided nesting bird and egg resources.

Although most archaeological reports have primarily focused on faunal resource management, floral resources were equally important, and there is evidence that these resources were also managed by Northwest Coast peoples. For example, the use of red elderberry fruit on the northern Oregon coast appears to have been quite extensive despite the fruit and its seeds being somewhat toxic. In fact, more than 40 berries and fruits were available in some part of the area to peoples of the Middle Holocene and include gooseberries, currants, salmonberries, serviceberries, and wild raspberries, blackberries, and strawberries. Likewise, many plants with edible roots or rhizomes were manageably harvested by peoples up and down the Northwest Coast during the Middle Holocene, including eelgrass (*Zostera marina*), Pacific cinquefoil or silverweed (*Potentilla pacifica*), wild caraway (*Perideridia gairdneri*), and hemlock parsley (*Conioselinum pacificum*).

Exploiting Plant Life in the Great Basin

The Great Basin is a region encompassing more than 115,800 square miles (300,000 square kilometers) between the Sierra Nevada of California in the West and the Wasatch Range of Utah in the East. To the north the region is bounded by the lower Snake River plain in Idaho and to the south by the Grand Canyon and the Colorado River. The region is composed of a series of large internally draining basins in which seasonal lacustrine marshes and lakes form, providing a rich variety of plant life that was regularly exploited during the Archaic period. Likewise, these basins are divided by a series of north-to-south ranges that also provide floral resources in a seasonal cycle from the basin floor to the upper mountain slopes along with riverine-based floral resources that grow in the perennial mountain streams. During the Archaic period, Great Basin peoples exploited plant life for a variety of reasons including subsistence, shelter, and technological purposes.

In the western Great Basin, for example, evidence indicates that 9,000–6,000 years before the present Great Basin peoples practiced a lakeshore lifeway adaptation that consisted of a generalized subsistence pattern emphasizing lacustrine and riverine food resources. By 6,500 years before the present evidence indicates that this lifeway pattern expanded to include a basic hunting and gathering subsistence regime that included the exploitation of plant life in the development of basketry and weaving. During this period ground-stone food-processing implements (e.g., manos and metates) also became common,

indicating an increased use of seed-bearing plants. These floral resources generally consisted of a variety of seed-bearing grasses, wetland plants, reeds, and desert scrubs, and there is some evidence of piñon nut exploitation in some of the upland areas at this time. Later a more dramatic series of changes in lifeway patterns took place, which is reflected by a major intensification in land use that included the nearly simultaneous appearance of intensive piñon nut procurement from upland camps and cache sites along with the establishment of seasonal alpine villages to exploit mountain floral resources. Coincident with these changes in the western Great Basin is evidence for the abandonment of some logistical hunting camps and the mass processing and storage of dryland seeds using specially prepared threshing floors. Throughout this period structures appear to have consisted of simple plant-based shelters (although caves were also used) along with the use of woven mats made out of reeds and marsh-based plant fibers.

Evidence for plant-life exploitation during the Archaic is also found in the central Great Basin, although the evidence is not as extensive. For example, analysis of paleofeces from Hidden Cave in western Nevada indicates exploitation of plant life throughout the Archaic period. Faunal and floral macrofossils, coupled with pollen analysis, evidences a dependence on wetland food resources augmented with small seeds from dryland plants. However, fecal steroid analysis indicates that the primary occupants of the cave were probably women, arguing for a differentiation in subsistence roles during the Archaic in this part of the Great Basin. This is most likely the result of the demanding environment of the central Great Basin at this time as compared to the western or eastern portions of the region where perennial mountain water sources were more common, requiring men to hunt for faunal resources while women gathered floral resources around centralized camps. Plant life was also exploited in the making of mats and clothing, as evidenced by the number of woven fragments and plant materials recovered from Great Basin cave sites. For example, at Danger and Hogup caves, the greater bulk of the deposits in the caves was made up of plant-life material, includ-

ing grasses, twigs, seed husks, and bulrushes, brought to the site by Great Basin peoples.

During the Archaic period, the people who lived in the eastern Great Basin followed similar social and subsistence practices as in the western part of the region. Initially most sites were located along prehistoric lakeshores in the basin floors. Later, Great Basin peoples also occupied upland regions that were situated in the piñon-juniper ecozones, allowing access to sage and grass communities as well as higher montane resources. Subsequently, corn agriculture was adopted from the Southwest in some areas of the eastern Great Basin, although evidence indicates that the adoption of agriculture in the region was short-lived.

Not only was plant life exploited for subsistence purposes, but Archaic peoples of the Great Basin also used floral resources in the construction of shelters, mats, clothing, and especially baskets. The exploitation of plant life in the construction of baskets was so important, in fact, that it has been possible to identify at least three distinct basketry-manufacturing regions. Each region had special characteristics that delineated it from other basketry-manufacturing styles, such as in the northern Great Basin where at least 13 different basket wall-construction techniques have been identified. These include at least 6 different coiling techniques and 7 basic twining methods such as close simple twining, close diagonal twining, and open simple twining.

Smaller Game in the Southwest

The Southwest is a region that extends from the Grand Canyon and the Colorado River in the north to the southern reaches of the Sonoran, Chihuahuan, and Mojave deserts. The western border of the region is bounded by the southern Colorado River and the Gulf of California, while the Guadalupe and Sandia Mountains loosely bound the eastern edge. Within this large region the geography and ecology vary greatly, although aridity is characteristic throughout the region. Prehistorically, the location of floral and faunal resources played a substantial role in the lifeway patterns of the people of the region because of these geographic and ecological factors. Prior to the domestication of various floral resources, especially corn, evidence indicates that prehistoric peoples of the region moved through different ecological zones in an annual cycle to take advantage of the seasonally available plant and animal resources. This lifeway pattern and its related technology are associated with what is known as the Archaic period and is represented by ground-stone seed-milling equipment and small atlatl-dart projectile points. This evidence indicates that the peoples of the region relied heavily on small game for much of their subsistence, which was supplemented by seasonal seed-bearing plants.

Smaller game played such a central role in Southwest Archaic peoples' lifeways that boundaries of foraging ranges moved to accommodate the shifting nature of resources in the region. This is evidenced by the variety of point styles and site locations found during the period. In

fact, Archaic period points have been recovered from a range of elevations and environmental zones across the Southwest, indicating seasonal population movements that exploited floral and faunal resources that occurred in distinctive ecozones along environmental and physiographic gradients. Based on projectile point distributions and data from obsidian sourcing studies, the scale of mobility and interaction across the region and between subregions was great. Lithic point styles that have been identified for the region and that date to the Archaic include unifacial and bifacial flaked points, long tapering-stemmed points, stemmed points, side-notched concave-based points, triangular concave-based points, and a wide variety of other lithic styles. All of these point styles appear to have been used in the procurement of relatively smaller faunal resources as compared to other regions, such as the Plains where Archaic peoples relied on bison and other large fauna. Procurement methods of Archaic peoples are little understood, although evidence indicates that a wide variety of techniques were used such as atlatls, spears, the bow and arrow, and various forms of traps and snares. Furthermore, because the region is marked by an arid ecosystem, Archaic peoples of the region were unable to rely heavily on floral resources until domestication and irrigation processes came into play at the close of the Archaic period.

For example, although evidence based on phytolith (archaeological remnants of plant cells) content of coprolites indicates that Archaic peoples relied on some noncultivated desert succulents (the agave and cactus families), other evidence indicates that the majority of the Archaic diet consisted of small game. The archaeological evidence shows that small game commonly taken by Archaic peoples of the Southwest include jackrabbit (*Lepus californicus*), cottontail (*Sylvilagus auduboni*), deer (*Odocoileus hemionus*), antelope (*Antilocapra americana*), quail (*Callipepla squamata*), and javelina (*Tayassu tajacu*) along with a variety of other small mammals and fowl. In the San Francisco Peaks region of northern Arizona, for example, the prehistoric inhabitants of the region relied heavily on both jackrabbits and cottontails. Furthermore, studies of body part frequencies and

bone damage in the archaeological assemblages have shown that Archaic peoples of the region did not suffer from the extreme dietary stress that later affected people in the region when reliance on domesticated floral resources became more prevalent.

Small game played such a key role in people's subsistence regimes of the Southwest during the Archaic that a majority of archaeological site locations from this period reflect this subsistence regime. For instance, sites from the Rio Grande Valley and surrounding area indicate that Archaic peoples lived in small or open-air structures for intermediate to short periods of time in localities that were positioned in areas favorable for the taking of small game. Evidence also indicates that some of these locations were selected to take advantage of small game population peaks, which occur in the late spring and summer, although there is little evidence of long-term storage use during the Archaic.

Archaeological site locations suggest that similar subsistence patterns occurred across the Southwest during the Archaic, although variation did occur depending on subregional specifics. In the Willcox Basin of southeastern Arizona, for example, during the Archaic period inhabitants maximized resource exploitation of diverse nonlacustrine (nonlake) semiarid habitats by following a vertical seasonal round (a cycle of moving from high regions in the summer to low regions in the winter year after year). Survey data from several dozen sites further indicates that residential camps were relatively sedentary, while specialized task groups established specific sites that took advantage of the basin's small game faunal resources. Reliance on small game continued to be of importance after the Archaic period, which is generally held to end 3,200–2,500 years before the present with the arrival of agriculture.

Hunting in the Eastern Woodlands

The Eastern Woodlands is a term used to designate the portion of North America east of the Great Plains and south of the boreal forests of the subarctic. Because this enormous region is so diverse, it is often divided into smaller units such as the Southeast, Northeast, and Midwest. Ecologically, the Eastern Woodlands are influenced by north to south trending temperature and plant-community gradients, which prehistorically created a variety of ecosystems throughout the region. Major physiographic features that also influenced these prehistoric ecosystems were the Coastal Plains, the Appalachian Mountains, the Central Lowlands in the interior north, and the Ozark-Ouachita hills in Missouri and Arkansas. Paleontological data indicates that the primary subsistence resources available in this region during prehistoric times were white-tailed deer, small game, fish, shellfish, various types of nuts, and wild seeds and roots.

The subsistence lifeway patterns in the Eastern Woodlands during the Archaic period (ca. 10,450–2350 years before present) consisted of a broad range of exploitative patterns ranging from hunting large and small mammals to fishing and gathering various floral resources, although

➤ DALTON TRADITION

Dalton projectile point from the Hardaway site near Badin, North Carolina, about 10,000 BCE. (Collection of the North Carolina Office of State Archaeology Research Center, Raleigh, NC)

The Dalton tradition is named after a distinctive type of lithic point found by S. P. Dalton in Missouri around 1948. Dalton points were thought to represent an early Archaic stage confined to Missouri, but current evidence indicates that these distinctive lithic points were ubiquitous throughout the Eastern Woodlands. The Dalton tradition is thought to date between 10,500 and 9,900 years before the present and was characterized by fluted points with lateral retouching usually obscuring all or most of each face. The point is commonly serrated, which has been taken to indicate that the main function of the point is for cutting meat. Small chert hammers, notched abraders, and end scrapers made on flakes are part of the tradition. Sites where Dalton tradition points have been recovered range from bluff shelters to open sites in the southeastern United States.

—Peter N. Jones

evidence indicates that the hunting of mammals played a significant role in most prehistoric Eastern Woodland peoples' diet. Projectile point sequences from the region begin with Dalton or Dalton-like points (10,700–10,200 years before present), and continue through side-notched (10,200–9650 years before present), corner-notched (9650–8850 years before present), and bifurcate forms (8850–7950 years before present), all of which were used in the hunting of mammals. Smaller side- and corner-notched points in a variety of regional styles followed these larger points until the end of the Archaic period, at which point evidence indicates that use of the bow and arrow began. It has been argued that these shifts in projectile point styles reflect shifts in how hunting weapons were used. For example, the shift from side-notched to corner-notched points is thought to have accompanied a change from thrusting spears to lighter darts propelled by an atlatl, while bifurcate forms are thought to have been adaptations for hunting particular forest game such as white-tailed deer (*Odocoileus virginianus*).

Evidence indicates that during the Early and especially Middle Archaic period, people practiced a hunter-gatherer economy based primarily along the floodplains and river bottoms where they hunted white-tailed deer, certain smaller game, and gathered seasonally available floral resources. This subsistence economy is thought to have been partially brought on by a change during the Middle Holocene from closed mixed deciduous forests to open xeric oak-hickory forests. This vegetation change and accompanying faunal change brought about a change in the overall subsistence economy of the prehistoric people of the area. For example, evidence from the Bluegrass site located in an interior upland drainage basin of southwestern Indiana suggests that white-tailed deer and hickory nuts became the basis of the subsistence economy during the Middle Holocene period.

Likewise, evidence from Martha's Vineyard (an island that is part of present-day Massachusetts) for this period indicates that people moved seasonally within their territory hunting white-tailed deer, with lesser meat taken from other species of birds, fish, and mammals. Similarly, evidence from the Koster site in southern Illi-

nois indicates that the people of the area relied primarily on hunting deer and small mammals, along with turkey and various migratory birds. In some regions archaeological data indicates that hunting primarily was a winter activity and that during summer months prehistoric peoples switched to more of a fishing and gathering subsistence economy. For example, the subsistence economy inferred from data of the interior Northeast indicates that during spring and summer people occupied riverbanks where shellfish, fish, turtles, and migratory birds were taken, while during the winter months hunting camps were formed to exploit deer and other terrestrial mammals.

Data from the Lamoka Lake site in central New York and dating to 4500 years before present indicates that the site was used over a period of several seasons and that white-tailed deer were the most commonly taken species. Similar evidence comes from the Cole Gravel Pit site located on a terrace above the Genesee River, south of the present-day city of Rochester. There is also some evidence that deer were transported whole to these sites where they were processed for both meat and marrow.

Toward the end of the Archaic, prehistoric peoples in certain parts of the Eastern Woodlands began to rely on other resources besides mammals, such as fish and freshwater mussels. Likewise, cultivation of various floral resources was adopted by peoples throughout the region to various levels by the end of the Archaic period. However, the hunting of small mammals continued to be a valuable resource, as evidenced by the Angel site. Located on the Ohio River and dating to the Late Archaic, this site has produced the remains of 26 different species of mammals, 5 of reptiles, 9 of fish, 32 of birds, 22 of mussels, and 15 of plants. The habitat preferences of the animals recovered from the site reflects a hunting subsistence economy based on the deciduous forest and forest-prairie edge.

➤ FISHHOOKS IN LATE ARCHAIC NORTH AMERICAN SITES

Curved hooks of shell and bone used as fishhooks have been recovered from sites throughout the Americas dating to the Late Archaic period. A majority of these sites are located in California, such as on the Santa Barbara Channel Islands, on the islands farther south and more distant from the mainland, and on the coast from Point Concepcion to Santa Ana. Bone hooks have also been recovered from the lower Sacramento Valley and from coastal shell mounds in Humboldt County in northwestern California. Similarly, curved bone hooks of an open-throated straight-shanked form have been recovered from Late Archaic Mississippian sites of the eastern United States as well as from the Great Lakes, the St. Lawrence Valley, and northern New England. The majority of these fishhooks are made from abalone (*Haliotis*) or mussel (*Mytilus*), although bone fishhooks have also been recovered. The ubiquity of these hooks throughout North America attests to the importance of fish in the subsistence regimes of Late Archaic peoples.

■ Introduction: Urbanization and Demographic Trends

The first cities were formed prior to 4000 BCE. By that time, cities and villages had become the dominant settlement types for much of the world (excepting North America, non-Egyptian Africa, and Australia). For those parts of the world where cities dominated, numerous new possibilities and problems arose from the fact that many people were living in close proximity to one another. In demographic terms, much of the population still remained in rural areas, which was essential for food production. However, power shifted to the cities; the city became the economically, politically, and religiously central type of settlement.

In order to study cities and the demographic patterns associated with urbanism, archaeologists use methods derived from the study of modern human geography. Of primary concern are settlement patterns: in other words, the spatial distribution of human settlements (of different sizes) and the changes in that distribution over time. By studying these spatial and temporal relationships, archaeologists can get a solid understanding of larger trends in human settlement behavior. This can be very revealing. For example, Indus Valley sites seem to disappear at about the same time that sites along the Gangetic Plain appear. By tracking changes in settlement patterns over time, archaeologists have been able to demonstrate that as river systems associated with the Indus Valley people disappeared, these people moved to other locations, and gradually settlements shifted toward the Gangetic Plain.

Within a given settlement system, there is bound to be a hierarchy of sites. These hierarchies are often reflected in the relative size of the sites. That is to say, large cities are most powerful, followed by medium-sized cities, followed by villages and hamlets. Usually larger centers hold the most economic power in a settlement system, but this is not the only type of power. Think of New York City in the modern United States; it is clearly the largest city in North America and holds substantial economic power in that continent. Yet it has no formal political power in Canada and Mexico, while a much smaller city—Washington DC—is the capital of the United States, not New York. Likewise, New York City has virtually no religious authority. The same is true for ancient settlement patterns, so it is very important for archaeologists to identify political, economic, and religious capitals within a given settlement system.

—Kevin M. McGeough

The Explosion of Cities in the Near East

Southern Mesopotamia, during the fourth millennium, experienced an increase in the number of populated sites. Scholars still debate the reasons for this increase, which seems to be too large to be explained by just normal population growth. Toward the end of the fourth millennium BCE a small region located near the head of the Persian Gulf experienced a sudden growth

EXPLOSION OF CITIES

in urbanism. One site, the city of Uruk, surpassed all others as an urban center surrounded by a group of secondary settlements. It covered approximately .96 square miles (250 hectares) and has been called the “the first city in world history.” The city was ruled by a man depicted in art with many religious functions. He is often called a priest-king. Underneath this office was a stratified society in which certain professions were held in high esteem. One of the earliest written texts from Uruk provides a list of 120 officials that includes the leader of the city, the leader of the law, the leader of the plow, and the leader of the lambs as well as specialist terms for priests, metalworkers, potters, and others.

At present it is not known how many other large urban sites existed in close proximity to Uruk due to the difficulty of excavating levels that date to this early period. To the east of south-

ern Mesopotamia lay a region located below the Zagros Mountains called Susiana. The name reflects the civilization centered on the site of Susa. There temples were built, and clay tablets were inscribed with numerals and word signs. Examples of Uruk-type pottery are found in Susiana as well as in other sites in the Zagros Mountains and in northern and central Iran, attesting to the important influence of Uruk culture. Uruk culture also spread into Syria and southern Turkey, where Uruk-styled buildings were constructed in urban settlements.

The period of Uruk expansion and cultural influence and possibly political influence came to an end around 3100–3000 BCE. The monumental buildings of the city were razed, and the religious quarters were leveled. The city remained, however, and new competing city-states emerged. During the approximate 550-year period that

THE SUMERIAN KING LIST

This text is best known from manuscripts dated almost 700 years after the end of the Early Dynastic period. The author assumes that there was only one legitimate divinely appointed ruler for any one period of time and that political hegemony was restricted to a limited number of city states.

“After the kingship descended from heaven, the kingship was in Eridug. In Eridug, Alulim became king; he ruled for 28800 years. Alagar ruled for 36000 years. 2 kings; they ruled for 64800 years. Then Eridug fell and the kingship was taken to Bad-tibira. . . . Then the flood swept over.

After the flood had swept over, and the kingship had descended from heaven, the kingship was in Kish. In Kish, Gushur became king; he ruled for 1200 years. . . . Then Kish was defeated and the kingship was taken to E-ana. In E-ana, Mesh-ki-ag-gasher, the son of Utu, became lord and king; he ruled for 324 years. Mesh-ki-ag-gasher entered the sea and disappeared. Enmerkar, the son of Mesh-ki-ag-gasher, the king of Uruk, became king; he ruled for 420 years. 745 are the years of the dynasty of Mesh-ki-ag-gasher . . . ; he ruled for 5 + x years. Lugalbanda, the shepherd, ruled for 1200 years. Dumuzid, the fisherman whose city was Kuara, ruled for 100 years. He captured En-me-barage-si single-handed. Gilgamesh, whose father was a phantom (?), the lord of Kulaba, ruled for 126 years. Ur-Nungal, the son of Gilgamesh, ruled for 30 years. Udul-kalama, the son of Ur-Nungal, ruled for 15 years. La-ba'shum ruled for 9 years. En-nun-tarah-ana ruled for 8 years. Mesh-he, the smith, ruled for 36 years. Til-kug (?) . . . ruled for 6 years. Lugal-kitun (?) ruled for 36 (or 420) years. 12 kings; they ruled for 2310 years. Then Uruk was defeated and the kingship was taken to Ur.”

followed, called by modern scholars the Early Dynastic period, written records inform us of the rise of the Sumerian cities of Adab, Kish, Shuruppak, Nippur, Umma, and Uruk as well as three foreign centers, one at Awan in the east, Hamazi in the north, and Mari located to the north on the Euphrates in Syria.

At the end of the third millennium a group of legendary epics was recorded in Sumerian cuneiform that relates to the exploits of early rulers. These accounts recount military victories and adventures. These narratives centered on the exploits of three kings from Uruk: Enmerkar, Lugalbanda, and Gilgamesh. Exploits of kings from other cities have at present not been discovered. The most important text describing the dynasties and central cities of southern Mesopotamia during the Early Dynastic period is called the Sumerian King List. Although composed at the end of the third and beginning of the second millennium BCE, it remains the most important source for understanding the rise of competing city-states. According to this text, kingship descended from heaven in a period before the flood. At that time eight mythological kings ruled for a total of 241,200 years. Another Sumerian composition called the “Rulers of Lagash” somewhat explains these fantastic numbers. It states that in the early days after the flood when kingship was reestablished, “the carefree youth of man lasted for 100 years and, following his upbringing, he lasted for another 100 years.” Kingship following the flood was then centered in local dynasties, which held political sway for short periods of time. At present it is not possible to determine which of these early rulers were real kings or legendary rulers vaguely recalled from now lost oral traditions.

By circa 2500 BCE urban centers of over 100 acres dominated the landscape of southern Mesopotamia. Land was held by private families and in estates controlled by the king and temple. Each city had a patron deity, and the city's temple functioned as a center for the receipt and redistribution of agricultural resources. The temple was the largest building in the city, and the god together with his or her household was thought to dwell there. Smaller temples for lesser deities were scattered throughout the cities.

Kings were both administrators and war leaders. The population was divided between speakers of Sumerian and a Semitic language that some scholars call proto-Akkadian. It is not known if ethnic rivalries contributed to the political alliances and warfare that characterized the Early Dynastic period.

The Uruk Period— Shifting Settlements

The Uruk period (4000–3200 BCE) marks the first large-scale urbanization of Mesopotamia. What is remarkable is the scale of the change seen between the end of the earlier Ubaid period and the end of the Late Uruk period. While the Ubaid period was marked by small sites of less than about 25 acres (10 hectares) evenly distributed over the alluvial plains of the Tigris and Euphrates rivers, the Uruk period sees the creation of cities up to about 620 acres (250 hectares) in size surrounded by hundreds of smaller sites and with a cultural impact that was felt as far away as Egypt and Afghanistan.

During the Early and Middle Uruk periods, settlement in the region became much denser and was centered on the city of Nippur (60 percent of the population of Mesopotamia lived near Nippur). A vast increase in both the number of sites (more than 100 around Uruk alone) and the size of sites was seen. Uruk at this time was already more than 175 acres (70 hectares) in size, and several other cities of more than approximately 75 acres (30 hectares) were already established. In the Late Uruk the center shifted to the city of Uruk (60 percent of Mesopotamians now lived near Uruk), and Uruk itself doubled in size to a massive 620 acres (250 hectares).

Ruins of the ancient Sumerian city of Uruk in present-day Iraq. (Nik Wheeler/Corbis)

It was now large enough to house 20,000–40,000 people, making it probably the largest population center in the world of its day. This initial shift south may have come as a response to a change in the courses of the Tigris and Euphrates and of their smaller tributaries as well as from the need to find room for the growing population. Furthermore, much of the southern portion of Mesopotamia in the earlier part of the Uruk period may still have been too marshy to support the agricultural capacity and population of large cities.

As the climate changed, populations in the north of Iraq also began to move farther south into the plains, particularly around the Zab and Diyala river regions. This period was also marked by expansion of the culture outside of the heartland of Mesopotamia into Syria, Iran, and Turkey. Initially, this expansion probably took the form of traders moving outside their normal sphere looking for new sources of trade goods and raw materials. Iran and the east provided materials such as chlorite and lapis lazuli, while the northwest provided timber, copper ore, and workable stone. At first these traders likely did not settle permanently in the region, but over time they came to establish dedicated neighborhoods of Mesopotamian expatriates living locally for at least part of the year in order to conduct trade. This is seen at sites in the north, where abundant workable stone was available, yet the inefficient clay sickles used in the south were being used alongside the more efficient flint sickles

used by local inhabitants. No corresponding shift of these populations southward into lowland Mesopotamia was seen, since they benefited more by staying on the periphery and providing the necessary trade goods. By the end of the Late Uruk period, however, this trade had become so productive that the cities of lowland Mesopotamia established permanent fortified colonies such as Habuba Kabira in Syria.

Rise and Fall of Minoan Civilization

Crete has been inhabited since at least the seventh millennium BCE, with the earliest settlements, probably of farmers, appearing at Knossos. The Early Minoan period is subdivided into three periods as originally designated by Sir Arthur Evans. The first two periods are called Prepalatial, as there is no evidence of large-scale communal buildings in Crete at this time. Instead, in the Early Minoan I and II periods, we see the rise of villages, notably at Haghia Triadha (Holy Trinity), Gournia, Knossos, Mallia, Mochlos, Myrtos, Palaikastro (Old Castle), Phaistos, and Vasiliki. The evidence from these sites suggests an undifferentiated society where most people were probably farmers who also took part in other crafts, such as pottery and weaving, during rests from fieldwork. Society seems to have been based on individual family units, with larger family units living together in village-like communities.

Changes occurred in the Early Minoan period that transformed the somewhat egalitarian farmer community into a political and social hierarchy. A hierarchy of settlements developed as some Early Bronze Age communities grew much larger than others. Knossos was always the largest, achieving a size of five hectares already in the Early Bronze Age. Phaistos, Mallia, and Mochlos, however, grew enough to absorb their neighbors. As early as the Early Minoan II and III periods, Palaikastro and Knossos begin to show elements of palatial architecture, such as monumental architecture and copious storage facilities. These new buildings were much larger than the simple homes of the Early Bronze Age Minoans, and it would appear that one of their original purposes was the storage of agricultural surplus. Orchard horticulture at these large sites indicated long-term planning and the emergence of a managerial class. The tombs of Mochlos, with a variety of elaborate tombs indicating great expenditures of wealth as well as more humble tombs, revealed that social differentiation was already beginning in the Early Minoan period.

Perhaps the most significant development in Minoan Crete is the rise of the palaces, which first occurred at the end of the twentieth century BCE—the Middle Minoan or First Palace period—at Knossos, Phaistos, and Mallia. The creation of the palaces indicates a new societal organization in Minoan Crete, with a supposed elite class (those who inhabited the palaces), occupational differentiation and craft specialization, and state control over long-term planning and trade, both domestic and foreign. The fact that the three earliest palaces are similar in plan also suggests that there was island-wide trade and communication by the Early Minoan III–Middle Minoan I period, indicating the beginnings of a homogeneous Minoan culture.

Another significant distinction between Early Minoan and Middle Minoan Crete was the rise of craft specialization. The high quality of such artifacts as metal objects, pottery, stone, and seals, as well as the elaborate palaces themselves, shows that professional stonemasons, metallurgists, and other artisans were now prevalent in Middle Minoan Crete. But there were other, more significant changes in Middle Minoan society,

specifically in foreign relations. During the Early Minoan III period, it is unlikely that Crete had any direct or long-standing trade links with Egypt. This picture changed dramatically in the First Palace period, when direct contacts emerged between Crete and Egypt. To the north, the main contacts occurred between Crete and the Near East. Crete's main trading partners were the western coast of Anatolia, especially the site of Miletos, and the islands off of Turkey's southern coast, especially Rhodes. The Minoans also made their first attempts at colonization outside of Crete; evidence suggests that the Minoans may have settled at their earliest known colony at Kastri on the island of Kythera during the Early Minoan II period. Other early colonies included the site of Trianda/Ialysos on the island of Rhodes, founded at the end of the First Palace period between Middle Minoan I and Middle Minoan II, and a colony at Iasos in mainland Turkey, settled from the Middle Minoan II period onward.

The trend toward larger settlements during the Early Bronze Age culminated with the rise of towns in the Middle Minoan period. Large towns such as Gournia and Palaikastro are distinguished by clearly delineated, somewhat regular streets creating blocks of multi-room, two-story houses. By the Second Palace period, such towns grew even larger and maintained community-oriented facilities such as public shrines. Some villages clearly defined their regional territory in the Middle Minoan period, notably Aghia Photia (Holy Light), which was entirely surrounded by a stone circuit wall punctuated by stone towers. The growing contacts and trade with regions outside of Crete, and especially with the Near East, prompted the growth of port cities.

On the whole, the First Palace period was a productive time for the Minoans. However, a volcano on nearby Thera experienced a massive eruption in approximately 1640 BCE, taking much of Thera with it and causing considerable real estate damage on Crete. But the Minoans emerged from the literal ashes of their Middle Bronze Age society to create an even more glorious Late Bronze Age society. This apex of Minoan civilization took place between Middle Minoan III and Late Minoan I, also known as the Second Palace period, roughly between 1640

and 1450 BCE. The Minoans rebuilt their palaces on an even grander scale, creating monumental structures at Knossos, Phaistos, Mallia, and Zakro. These palaces shared a number of similar features and styles, which can not only be attributed to the fact that they served similar functions, but also to close connections that emerged throughout Crete during this period. Island-wide communications are also evident in the pottery dating from that period. Coarse wares (simple pots used mainly for food preparation and transportation) from eastern and central Crete show up throughout the island, indicating island-wide trade in specialized commodities.

Perhaps as a result of improved communications and contact, or perhaps resulting in them, social organization became even more elaborate during this period. At the pinnacle of this society, as previously mentioned, are the palaces, although who actually ran the palaces is still a matter of debate. Greeks who lived 1,000 years later told stories of three brothers—Minos, Rhadamanthys, and Sarpedon—who were the kings of Knossos, Phaistos, and Mallia, respectively. By contrast, the Bronze Age evidence seldom depicts kings; rather, females predominate in the artwork from that period, leading some to suggest that Crete was ruled by women, either in the function of queens or priestesses.

Regardless of who ran the palaces, by the Second Palace period a new level of bureaucracy emerged in Crete, visible in a new architectural structure—the villa. There were three distinct types of villas throughout Crete: country villas, which were fairly independent entities; manorial villas, which were associated with towns and villages; and urban villas, which were located in the cities, including one located right beside the palace of Knossos itself. The country villas were equipped for industrial production, storage, and religious/ritual use as well as domestic activities. The manorial villas were usually more oriented toward storage, and the urban villas could provide little more than a household unit with possible religious functions. However, all villas seem to have performed one common function—to serve as a liaison between the palaces and the rest of the community. Thus, as opposed to the roughly two-tiered bureaucracy of the First Palace period, the Second Palace period

appears to have had a three- or even four-tiered system, with palaces at the top, villas and cities in the middle, and villages and farmlands at the bottom. Nevertheless, this social hierarchy does not seem to have been as exclusive as those in many contemporary societies. The boundaries between palace and village, or villa and village, were not so clear (at least in modern excavations), suggesting a certain amount of free access on the part of all members of society to the areas of power. This freedom of access probably not only contributed to the general lack of warfare on Crete in the Second Palace period, but also served to homogenize the society, whereby all members engaged in similar religious rituals and bureaucratic practices.

The general peace and stability of Crete at this time are particularly significant in light of the general growth in population discernible in the seventeenth and sixteenth centuries BCE. Ultimately, the Minoans decided to stretch out into the eastern Mediterranean, continuing the process of colonization that they had begun in the preceding era. Many of the Cretan colonies were new foundations, whereby the Minoans settled previously uninhabited land. At other sites, the Minoans settled down among the native inhabitants, bringing aspects of Minoan culture such as pottery and architecture into the native culture. Often these colonies served not only to relieve overpopulation in Crete, but also to establish trade networks throughout the Aegean.

Beyond the Aegean, Minoan Crete had increasingly frequent contact with the great powers of the Near East during the Second Palace period. In Egypt, records from the reigns of Queen Hatshepsut and King Thutmose III mention “gifts” (more likely items for trade) brought by the “Keftiu,” who appear in Egyptian wall paintings dressed in Minoan-style garb. Pottery from the island of Cyprus and the eastern coastal areas of the Mediterranean appeared in increasing quantities in Crete during the seventeenth through fifteenth centuries BCE. Likewise, Minoan pottery began to appear in quantity on Cyprus in the Late Minoan IA period, and from Cyprus to Canaan to Egypt by Late Minoan IB.

Such was the power and influence of Minoan Crete at its peak. What brought an end to this great power in the middle of the fifteenth

century, at the break between Late Minoan IB and Late Minoan II, was not another natural disaster. To the contrary, invaders from the north—the Mycenaeans—brought about the end of the Minoan civilization.

The Early Bronze Age—The Rise and Fall of Urbanism in the Levant

The Early Bronze Age (EB), which runs from approximately 3300 BCE to 2300 BCE and is divided into three discreet periods (I, II, and III), marks the beginning of urban life in the Levant. After millennia of hunting and gathering followed by the first experiments with agriculture, groups of people began to establish the first semisedentary centers in the Neolithic and Chalcolithic periods. By the end of the Chalcolithic period, large groups of pastoral nomads living

on the margins of the Negev Desert had begun to establish permanent centers where their elites lived, where regular religious events were held, and where their dead were buried. With the end of this period, there appears to have been a change in climate that resulted in these marginal

areas becoming more inhospitable. The survivors of these cultures eventually settled along the more fertile coastal plains and lowlands and established the first urban centers. Over the thousand years of the EB I-III, these large villages develop into numerous small cities and then into a

handful of well-fortified cities before finally collapsing at the end of the EB III and returning to pastoral nomadism.

At the beginning of the Early Bronze Age, a dramatic growth is seen in the number of settlements in the region and in the density of population. Areas that had been heavily populated in the preceding Chalcolithic period are either partially or totally depopulated. Even when sites are found in these regions, they appear on virgin soil. New sites, however, pop up all over the rest of the Levant.

It is likely that the economic focus at this time had switched from pastoral herding to full-scale agriculture. The sites consist primarily of unfortified villages in the regions of the country with the most fertile but easily maintained soil. Sites were generally located so as to best control communication routes and access to water. Given that the technology to build plaster-lined cisterns was not yet available, sites were limited in general to locations with an ample natural supply of water.

By the end of the EB I, the population of the region had grown quite dramatically. This would have created new pressures and new incentives to build larger, more complex centers. Furthermore, the EB I corresponds with the rise of dynastic Egypt. This resulted in an even greater need to control access to resources and communication routes. Many of the sites founded in the EB I became major population centers during the EB II. Some of these centers grew at the expense of smaller sites, which were depopulated as their people moved to the larger urban centers. By the time urbanization in the region had peaked during the EB II, more than 1,500 acres of urban area existed in the Levant, representing a population of at least 150,000 or more. For the first time many of these centers began to be substantially fortified, with sites having city walls 9–13 feet (3–4 meters) thick and towers.

The EB III sees a dramatic change in the state of urbanization. Many of the EB II centers are either depopulated or destroyed, and the population becomes centered primarily in about 20 major centers. It is unclear why this occurs, but it likely stems from a combination of environmental factors such as decreased rainfall and from political factors such as competition for land and resources between the burgeoning

city-states. Fortifications around sites are dramatically strengthened at this time and sometimes even doubled in size. Massive cyclopean stone walls and glacis are seen for the first time, as are massive monumental gateways. These all require massive amounts of well-regulated manpower and resources, suggesting a strong centralized authority in these cities. Not surprisingly, as a result, for the first time large palaces are seen in these centers.

Despite this major series of developments, with the onset of the EB IV/Middle Bronze Age I there is a complete collapse of the urban system and a return to pastoral nomadism. It is not known what the cause or causes of this collapse were. Suggestions have included the collapse of the Old Kingdom in Egypt and the subsequent period of chaos that ensued immediately to the west, a dramatic change in climate including a drastic change in rainfall, or the appearance of foreign groups from the north and east. It is unlikely that any one of these was the single cause and more likely that all of these played a role, as did other factors that may also have driven the collapse of the Old Kingdom in Egypt and the need for groups to migrate south and west from Mesopotamia and Anatolia.

The Intermediate Bronze Age, circa 2300–2000 BCE — A Return to Nomadism

The Early Bronze (EB) Age (ca. 3300–2300 BCE) marked the beginning of urbanization in the Levant. At the end of the EB III (approximately

2300 BCE) after about 1,000 years of city dwelling, the entire urbanized society collapsed and reverted to pastoral nomadism. Numerous explanations have been offered for this dramatic change in lifeways, including the appearance of new ethnic groups, warfare, and climatic change. None of these alone explains the collapse, but it would appear that a combination of all of these factors may underlie it.

The end of the EB was marked by a period of declining population, centralization of settlements, and fortification building. It is likely that these phenomena were linked. Without any historical documentation it is impossible to be certain, but it appears that the end of the period was marked by intercity warfare that led to this centralization of populations in large defensible centers rather than spread across the landscape in small villages. Some evidence may be seen not only in the stronger fortifications at these sites but also in the constant rebuilding and repairing of them.

There is also virtually no evidence during the EB III of any form of trade between Egypt and the Levant. This would have caused economic hardship for the region since trade with Egypt had previously been the impetus behind the creation of cities in the Levant. This period is contemporary with the end of the Old Kingdom, when the Egyptian economy was beginning to be spread thin by its immense public projects and when power was becoming less centralized with the king and more localized with the nomarchs. There is evidence toward the very end of the Old Kingdom that the Egyptians campaigned against the so-called sand dwellers in the Levant. These campaigns may be the cause of many of the destructions and abandonments of cities at the end of the period. Not long after these events, the Old Kingdom itself collapsed. While this would mean no further attacks by the Egyptians, it would also mean no trade.

In addition, it is thought that the end of the EB may have been marked by a dramatic decrease in rainfall. This would have placed the urbanized population under great stress. The cities were entirely reliant on agriculture for food, and given the primitive technology of the day, a significant drought would have resulted in chaos. Given the increase in population in the area

with the growth of urbanization, it would have been highly susceptible to climatic and population pressures. Such pressure may be behind the appearance of new populations in the region looking for alternative sources of food, trade, and land. Contemporary documents from Mesopotamia first mention the appearance of Semitic nomads called Amurru (Westerners). These people may come to form the core of the Semitic population of the Levant from the Middle Bronze Age onward. Other groups including people from the Caucasus begin to appear in the region, bringing new technologies as seen in the appearance of a highly burnished and poorly fired ceramic known as Khirbet Kerak, Red-Black Burnished Ware, or Early Trans-Caucasian Ware. The appearance of these pastoral groups in the region would have only added to the stresses already evident. The combination of these factors likely made the collapse of the EB civilization of the Levant inevitable.

With the collapse of the urban culture of the EB, the groups best able to cope with the change in climate, lack of foreign trade, and the much smaller population were the pastoralists who had been living alongside the city and village dwellers. These people were joined by the new groups of pastoral nomads who had entered the region at the end of the EB III. Instead of having large population centers, these people lived in small villages (no larger than 75 people). Virtually all of the major city sites were abandoned, and if there was a continuous occupation, it was on a very minor scale. Their villages were seasonal, and they would have moved with their flocks in order to take advantage of wet seasons in the moister parts of the region and grow crops to supplement what could be garnered from their sheep and goat herding. These small groups would have interacted with other small related kin groups who shared a common material culture. They would gather infrequently to bury their dead in one of the numerous vast cemeteries characteristic of this period. This would explain the very regional nature of much of the pottery and the varying forms of burial seen during this period. The differences are quite drastic from the north to the south of the Levant and may suggest that the groups were quite isolated and limited to small territories.

The Late Bronze Age

In Egypt the Late Bronze Age marked the resurgence of independence with the repulsion of the Hyksos and the beginning of the New Kingdom. After years of being dominated by the Canaanite Hyksos, the Egyptians made their presence known in the Levant by regularly campaigning there and by establishing administrative centers and fortifications along the major communication routes. They also prevented the local Canaanites from rebuilding their own fortifications.

The Canaanite cities paid heavy tribute to the Egyptians and bowed to their trade demands in order to avoid being crushed. The only hope for these cities was to ally with Egypt's enemies. Initially this was the Anatolian state of Mitanni. Mitanni became Egypt's paramount rival during the early part of the New Kingdom (Eighteenth Dynasty). This rivalry culminated in the Battle of Megiddo when Thutmose III defeated Mitanni and a coalition of Canaanite city-states. This left Mitanni weakened, and the Hittites who had an empire based in central Anatolia became the new threat around the mid-fifteenth century BCE. The Hittites and Egyptians eventually also came to blows at the Battle of Kadesh during the reign of Ramses II. The battle resulted in a draw, and both sides decided that an alliance would be more useful given the changes occurring in the region at the time.

Between the periods of regular military campaigning typical of the early rulers of the

Egyptian Eighteenth Dynasty and those of the Nineteenth Dynasty was the Amarna period. This period was marked by a stretch of both relative calm in the region and visible weakness on the part of the Egyptians who opted to stay in Egypt and run their little empire from their heartland.

Correspondence between the vassal states in Canaan and the Egyptian Crown were preserved in the form of hundreds of cuneiform tablets found at the site of Tell el-Amarna. These Amarna Letters show a complicated web of diplomacy that existed between Egypt, the Levant, and Mesopotamia at the time. They also highlight a key issue of the day for the Canaanite cities. Every time the Egyptians campaigned through the region or demanded more tribute, more and more economic pressure was placed on the Canaanites. The constant demands of the Egyptians meant that much of the wealth generated there was finding its way back to Egypt and not reaching the locals who lived in a constant state of economic depression. Furthermore, many of the Canaanites were being forcibly relocated to serve in Egypt, thereby depopulating the region. Given that the Egyptians appear not to have allowed the Canaanites to fortify their cities during the Late Bronze Age, the threat of raids by both their Egyptian overlords and local banditry would have been constant. This combination of economic and other pressures drove many to abandon their urbanized lives and move to the hills. Enough of these disenfranchised and frustrated people existed to form an entire substratum in Canaanite society. These groups of people were called the Habiru. They wandered the hill country, set up small settlements, and harassed the cities through both banditry and more organized means. Some of these Habiru may have eventually come to form the nucleus of what will be the ancient Israelites. It is clear from the Amarna Letters that the region was constantly in flux thanks to intercity warfare and the existence of these Habiru.

In the Aegean world two great cultures had existed simultaneously during the Bronze Age. The Minoan and Mycenaean cultures thrived during the Middle Bronze Age, with the Minoan cultures of Crete helping in the development of the Mycenaean culture of mainland Greece. Un-

fortunately for the Minoans, their civilization collapsed around 1450 BCE possibly as a result of the explosion of the Thera volcano. The Mycenaeans managed to maintain their civilization, even taking over Crete, until the thirteenth century BCE when widespread destruction of their centers was seen. It is unclear why the Mycenaean society collapsed, but a number of suggestions have been made including outside threats, economic issues, intercity warfare, and drought. As a result, the military and elite of this society were forced to abandon their palaces and seek new homes and new ways to exist.

It appears that some of these former Mycenaeans initially fled to Cyprus and coastal Anatolia, where they came to be known as the Sea People. These people brought about the collapse of the Hittite empire (which had also been affected by severe drought), conquered parts of the coastal Levant (including the important city-state of Ugarit), and tried to invade Egypt only to be repelled during the reigns of Merneptah and Ramses III. Some of the survivors of these invasions came to settle on the coast of Israel and became the biblical Philistines of the early Iron Age.

In the wake of the attempted Sea People invasion, the Egyptians campaigned in the Levant and destroyed numerous major urban centers. With the general mayhem that ensued, the Levant found itself to be a hospitable place for disenfranchised groups to claim a stake, and alongside the Philistines we see the establishment of what would eventually become the states of Israel and Judah in the form of the early Israelite settlement. Not long after this the area that is now Jordan would see the establishment of the early forms of the states of Edom, Ammon, and Moab.

In Syria, this period saw the rise of the Arameans who in the Iron Age came to be major players on the geopolitical scene. They were originally a nomadic people but over time came to settle alongside and then within the established urban communities of the region. Initially, they acted as mercenaries for the various powers of the day.

In Mesopotamia proper, the Old Babylonian empire was brought to an end by the Kassites who conquered Babylon around 1595 BCE. This

Ruins of the ancient city of Mycenae, center of a large and powerful Greek civilization that existed between the seventeenth and twelfth centuries BCE. The remains of the city were first excavated by German archaeologist Heinrich Schliemann in 1876. (Ken Russell Salvador)

Indo-European group probably came from what is now Luristan. They had been a peaceful neighbor to the Babylonians, but thanks to an influx of population from the warlike horse-using nomads of Russia they rose up against the Babylonians. It is at about this same time that the Harrapan civilization of the Indus Valley collapsed, possibly also due to invasions by Indo-European horse warriors. In Mesopotamia proper as the Late Bronze Age drew to a close, changes in the regional balance of power led to the rise and fall of several great powers. The Assyrians under Shalmeneser I (ca. 1275 BCE) conquered Urartu in Armenia and Hanigalbat, the capital of the Hurrians. These events may be behind the alliance formed between Egypt and the Hittites, who feared the onslaught of the new Assyrian empire. The Kassites in Babylon also feared the Assyrians but managed to hold out against them until finally in 1157 BCE Babylon was conquered by the Elamites of Iran, who had also taken advantage of this period of general unrest to rise to the forefront.

The Late Bronze Age marks a turning point in the history of the Near East. It is a period when the region becomes far more cosmopolitan in its politics. With the collapse of the Mycenaean civilization and the appearance of mounted warrior cultures from Russia, the region is dramatically

affected by the appearance of Indo-European populations. These new groups stir up the politics of the region and cause much of the unrest underlying the various foreign policies of the great powers of the day. The near constant warfare, political maneuvering, and resulting economic effects created opportunities for the various disenfranchised populations such as pastoral nomads (e.g., the Arameans) and displaced groups (e.g., Sea Peoples and Habiru). As a result, the end of the Late Bronze Age saw a complete change in the status quo of the region. By the end of the Late Bronze Age the Mycenaeans, Mitannians, Hittites, and Hurrians had all ceased to exist as independent cultures. Some of the Mycenaeans may have become the Philistines. The remains of the Hittite empire formed small rump states in the southern part of the former empire that during the Iron Age eventually became important Aramean city-states. The period saw the rise of the Elamites and the Assyrians at the expense of the Kassites and also saw the beginnings of what would become, thanks to the Hebrew Bible, some of the more well-known cultures of the Iron Age Levant.

Urban Life in the Indus Valley

The Indus River valley was the location of a great urban civilization of the third and second millennium BCE. Like ancient Egypt and Mesopotamia, civilization in the Indus River valley was

built around large cities, with a well-developed trading system, agriculture, and metalworking. Unlike the other two cultures, that of the Indus River valley was unknown to modern archaeologists until chance discoveries led them to the key locations in the 20th century CE.

The civilization of the Indus River valley is known as the Harappan civilization, the Indus civilization, or the Indus Valley civilization. Radiocarbon dating indicates that it arose around 2500 BCE in the greater Indus River valley of Pakistan and northwest India. The two major cities of the culture were Harappa and Mohenjo-daro. The existence of a prehistoric civilization in the Indus River valley had not been known, so the discovery of square seals during the nineteenth century CE in northwest India caused British archaeologists some puzzlement. The hieroglyphs found on the seals could not be read by the archaeologists, so a search for more artifacts continued.

In 1921, Sir John Marshall, the director general of the Archaeological Survey of India, sent his colleague, Rai Bahadur Daya Ram Sahni, to excavate the ruins at Harappa. At around the same time, Rakal Das Banerji of the Archaeological Survey of India was digging at Mohenjo-daro, 400 miles away. When Banerji and Sahni discovered similar seals at the two sites, the archaeologists realized that they represented the remains of a unique civilization. By 1924, Marshall could announce the discovery of a previously unknown civilization. For nearly a decade, intensive digging occurred at both sites, as well as at others that were discovered later.

Archaeologists realized that the Indus River valley civilization spread over a large part of modern Pakistan and northwest India. Settlements were found that dated back to 2800 BCE. Between 2600 and 2500 BCE, a great social change occurred. Urban centers that had not existed before came into being. The people survived on a mixed agricultural economy. They grew barley and wheat, with possible evidence of rice cultivation as well. They also cultivated chickpeas and field peas. The fruits and seeds of various wild plants were also gathered, including grapes and jujube. Some of the earliest known use of cotton dates to the Indus River valley civilization as well. In addition, the people of the In-

dus River valley raised a species of humpbacked cattle. Other animals that they raised included sheep, goats, pigs, and dogs, and chickens were domesticated. Fish were an important part of their diet, and evidence indicates that urban centers near the sea traded fish to inland centers.

Harappan sites show a remarkable uniformity in building techniques and urban design across a very large area, suggesting some form of widespread centralized government. The uniformity of buildings and the lack of palaces or temples within the cities also suggest that there were not large distinctions in class. Large urban centers like Harappa and Mohenjo-daro were surrounded by agricultural villages that presumably provided the cities with food.

Trade played an important role among the Harappan people. Besides trading food products among themselves, they also maintained trading relations with the people of central Asia. Raw products, like gold, silver, and copper, and various minerals and precious stones were obtained. They produced metal products, like copper goods, and ceramics and pottery. Information about trade with the people of the Persian plateau is uncertain, but a thriving trade was carried on with the cities of Mesopotamia. The Mesopotamian trade was carried on through ships, and Mesopotamian records refer to Meluhha, their name for the Indus River valley people. Products sent to Mesopotamia include agricultural goods and carved stones and different artistic items, including statues.

The hieroglyphic writing of the Indus River valley people still has not been deciphered. Archaeologists have studied the drawings that have been recovered, however, and have developed theories about the religious life of the people. Their gods appear to have animal characteristics as well as plant characteristics. The idea of gods with these characteristics is one that became common in Hinduism, causing many to speculate that the Indus River valley religion played a role in the origin of that religion.

Water also played an important role in the Indus River valley civilization. Among the huge public buildings at Mohenjo-daro was a public bath, known as the Great Bath. Many of the private homes in the urban centers surveyed also included bathing facilities. Bathing and cleanli-

ness appear to have played a religious role in the Indus River valley civilization.

By ca. 1750 BCE, the Harappan civilization had begun to decline. Many cities had been abandoned, or their population had declined to a very small number. One explanation offered for this was that the surrounding countryside had been devastated by the deforestation caused by a population and building explosion. Other explanations, like a devastating flood or destruction caused by invading Aryan tribes, have been disputed. Further details about the civilization remain to be discovered by further investigations of the relics of the Indus River valley civilization.

Mohenjo-Daro and the Cities of the Indus River Valley

The city of Mohenjo-daro, meaning the “hill of the dead,” was the largest settlement of the Indus River valley culture that is believed to have originated in the third millennium BCE. The city’s ruins, on the west bank of the Indus River about 200 miles north of Karachi, Pakistan, display evidence of a careful urban design combined with a sophisticated infrastructure that was undreamed of in the contemporary river valley civilizations of Egypt and Mesopotamia. Noted for widespread and seasonal flooding, Mohenjo-daro peaked from 2500 to 1700 BCE.

Archaeological evidence suggests that Mohenjo-daro emerged around the late fourth century BCE. Along with its sister city Harappa in the north, Mohenjo-daro was the southern capital of the Indus River valley civilization. The Harappans, who inhabited the city, were an agriculturally based people who cultivated barley

and wheat. Originally begun as agricultural villages located alongside the Indus River, Mohenjo-daro reorganized itself to accommodate frequent annual flooding.

The Harappans made a dizzying leap from villages to cities between 2600 BCE and 2500 BCE. Quite suddenly the dynamics of the community changed, including commercial centers with high levels of municipal control, complex social organization, specialized occupational structures, administrative expertise, and such tools as a writing system, mathematics and geometry, survey instruments, and standard weights and measures.

As Mohenjo-daro evolved, its economy widened. While agriculture remained its mainstay, organized crafters, including brick makers, builders, and potters, coexisted with the farming people. At its high point, Mohenjo-daro boasted approximately 35,000 inhabitants. Although there were other locations of comparable size and importance, Mohenjo-daro was a principal Indus River city, covering more than 200 acres and measuring more than two miles around. Like most Indus cities, it had two principal and functionally disparate districts, each built on a huge mud-brick platform that raised it above the annual floods. To the west stood the 40-foot-high citadel, measuring 1,260 feet by 750 feet. Fortifications survived at the southeastern corner, and the entire platform may have been enclosed by a wall.

The city was home to a collection of public and private buildings. Archaeological evidence suggests that public buildings included a large granary, an assembly hall, a college, and a ritual tank. Noteworthy among the public buildings was the so-called Great Bath, about 39 feet by 23 feet in size and 8 feet deep. It was built of fired bricks laid in gypsum mortar and sealed with bitumen.

The well-thought-out grid-patterned city gives early indications of South Asian urban planning, as the residential lower city occupied a more extensive platform than the city to the east. The lower city was set out on a north-south east-west grid of properly drained brick-paved streets, 30 feet (9 meters) wide, forming rectangular urban blocks measuring about 400 yards by 270 yards (366 by 247 meters). Tightly packed courtyard

houses and places of business, all built of fired brick, faced the streets. It is likely that internal walls were plastered, and most houses had stairs leading to either a second story or a flat roof. The houses normally had a private bathing area supplied with water from a well on the property and also had a properly drained toilet. A secondary grid of narrow service lanes subdivided the main blocks, and chutes from most residences were connected to a system of covered sewers, more evidence of well-developed municipal controls that still cannot be found in many Asian cities. Harappa and many other Indus River sites are almost identical to Mohenjo-daro in layout and organization, which indicates that at the peak of the civilization regional centers may have been built to a standard city plan.

The remarkable civilization remained unified for nearly 700 years. After 1900 BCE, as a result of an overexpansion of its trade networks, the city began to disintegrate gradually. Within 150 years, Mohenjo-daro's efficient urban government had disappeared. Ecological factors augmented the administrative breakdown. Recent research indicates that most protohistoric cultures suffered three centuries of persistent drought from about 2200 BCE, perhaps activated by a sudden global climate change. The passing of the Indus River cities can also be attributed in part to changing river patterns that upset a river-based agricultural and trade economy that had already outgrown its strength.

Mohenjo-Daro's Sewers

Almost all historians today regard the sewage system of Mohenjo-daro as the largest and best-built sanitation system among contemporary urban centers. It is easily comparable with present-day drainage systems of South Asian countries such as Pakistan, India, and Bangladesh. Even today in most of Pakistan and India the same model of drainage is followed what was used in Mohenjo-daro. This indicates the advanced engineering and urban planning of the Indus Valley civilization.

The sewage system of Mohenjo-daro was comprised of ducts covered with bricks and draining pipes running the length of the usually unpaved streets connected by small chutes with most of the houses. These ducts, U-shaped in cross-section, opened into the main collecting channel of the avenue wherefrom the waste was disposed of into either a landfill or a lake. The main collecting channel was covered with bricks, and access to the channel was gained by man-hole covers when cleaning was required. Historians have different opinions about the land used for the disposal. Some conclude that sewage was simply dumped, while others argue that this waste was disposed of in a way to increase soil fertility. The latter opinion is more likely, as the permanent standing water would produce an unpleasant odor throughout the city.

This complex drainage system also supports the view that all or at least most of the houses in Mohenjo-daro had indoor water facilities. Evidence tends to confirm the presence of wells for their daily household water consumption. Usually, each house had a private bathroom with a shallow basin made by the arrangement of bricks in it as well as a sophisticated toilet with brick seats. Archaeological excavations from Mohenjo-daro also prove the presence of a great bath that served as a public bathroom connected with the draining system in the same manner as private bathrooms.

Although it is logical to say that there might have been a public sanitation department in Mohenjo-daro with specialized workers who were responsible for the maintenance and repair of such a large and complex sewer system, no clear-cut evidence has been found to prove this.

THE GREAT BATH OF MOHENJO-DARO

Great Bath at Mohenjo-daro. (J. M. Kenoyer, Courtesy Dept. of Archaeology and Museums, Government of Pakistan)

A large bathing platform covering 18,298 square feet (1,700 square meters) named the Great Bath of Mohenjo-daro was excavated in the northern sector of the Acropolis in 1925. This Great Bath was thought to be a place for ablutions by priests and others. There were a series of eight bathing compartments in two rows on either side of the Great Bath. The Great Bath had a huge well and lots of structures in it; fresh water was obtained for use here. The concept of deliberate extravagance in the use of water can be seen through the Great Bath.

—Muhammad Aurang Zeb Mughal

It seems most likely that some formal agency was responsible for monitoring the system. Such a well-engineered drainage system represents not only the engineering skills of the people of the Indus Valley civilization but also the importance that sanitation and cleanliness played within their culture.

The Bactria-Margian Archaeological Complex

The Bactria-Margian Archaeological Complex (BMAC) is a Bronze Age culture that established a sedentary lifestyle in central Asia from about 2200 BCE to about 1700 BCE. “Bactria” and “Margian” are both terms that the ancient Greeks used to refer to the region. The culture is also known as the Oxus civilization, since many of the sites are located along the Amu Darya (which was called the Oxus River by the ancient Greeks). Archaeological evidence for this culture has been found in modern Turkmenistan, northern Afghanistan, southern Uzbekistan, and western Tajikistan.

The BMAC was one of the earliest cultures to urbanize in central Asia. The largest of these sites is Namazga-Tepe (or Namazge-Depe), which at its largest extent was approximately 173 acres (70 hectares) in size. In general, BMAC towns had circular plans and were well fortified, indicative of warfare in the region. Monumental architecture has also been uncovered in many of the cities. Some scholars have suggested that these cities were established in response to in-

teractions with cities in the Near East and the Indus Valley, and evidence for contact with those regions is well attested through BMAC artifacts (such as stamp seals) that have been found in those regions.

Namazga-Tepe has been well excavated, and archaeologists have identified distinct zones within the city, including living quarters, industrial quarters, and cemeteries. A smaller town, Altyn-Depe, has also been excavated and was about 74 acres (30 hectares) in size. Other cities are not as large, and it has been suggested that Namazga-Tepe was the capital and Altyn-Depe was a secondary or regional capital. However, the size of sites does not always correspond directly with their political power (compare New York City with Washington, D.C., for example), and one should be cautious in reconstructing this kind of political relationship.

The people of the BMAC relied heavily on irrigation agriculture; this was their primary means of subsistence. As with urbanization, it is likely that they learned how to farm from interaction with Mesopotamia or the Indus Valley civilization. Their primary crops were barley and wheat, both of which were initially domesticated in the Near East. This may have been one of the areas through which wheat and barley agriculture spread from the Near East to China. There is little doubt that the development of farming allowed the BMAC to become sedentary. However, even after the establishment of cities, the BMAC maintained close contact with the Andronovo culture, who were pastoralists. Likely the BMAC gained sheep, goat, horse, and dairy products from the Andronovo and themselves offered agricultural products in exchange.

—Kevin M. McGeough

➤ WERE THE BMAC INDO-ARYANS?

One of the most controversial issues in the archaeology of South Asia is the question of where the supposed Indo-Aryan invaders who brought Vedic culture to India came from, if they ever existed outside of South Asia. Based on references in Vedic texts and linguistic evidence, some scholars have suggested that the Bactria-Margian Archaeological Complex (BMAC) may have been the homeland of the Vedic peoples. Unfortunately, little evidence for the language of the BMAC people exists, and it is very difficult to associate material culture with language and ethnicity, so this must remain, at present, an unproven theory.

Domestic Waste

Although the ancient methods for the disposal of domestic waste might be considered unhygienic by modern standards, it is clear that an attempt was made to effectively manage the by-products of everyday living. Domestic waste can include a broad range of material yet typically contains ash, excrement, items considered beyond repair, and the refuse from food preparation. Refuse was commonly dumped in the open, although occasionally special storage or disposal was arranged.

Streets, courtyards, fields, and rivers served as convenient toilets and dumps. While at sea, waste (including excrement) was simply discarded overboard. In the case of river or sea dumping, the debris would be carried away; in a hot climate, insects and the sun could obliterate all traces of uncovered feces and organic waste. In some settlements, the dumping into exterior spaces resulted in ever-rising street levels, such that it necessitated stepping down into the buildings and the eventual rebuilding of the structure at a higher level. Residents near the outskirts of town simply dumped waste over the town walls.

Although there is abundant archaeological evidence for constructed street drains in many urban settlements, we have only a few examples of built interior toilet facilities. Most large drains appear to have been municipal projects designed to sluice water and liquid waste outside the city walls. The drains varied in construction from simple unlined sluices to fully waterproofed, carved, and covered stone troughs. Some wealthy private structures contained sewage drains and even toilets and cesspits, but the average residential structure appears to have done without. One exception might tentatively be identified at Tell Beer-sheba (Building 2309) in which a plaster-lined stone drain was discovered leading from a side room. It is possible that some residents used portable chamber pots that were later emptied outdoors, although no vessel has been definitively identified for this specific purpose. A portable toilet stool from the Eighteenth Dynasty tomb of Kha, a senior official in the hierarchy

› DOMESTIC WASTE DISPOSAL AND DISEASE

Epidemic disease was an accepted part of life in the ancient world and may have been perpetuated by waste disposal methods. Urban scavengers such as rodents, dogs, and pigs had easy access to domestic waste. If the scavengers were a part of the local diet, it is possible that the meat transmitted diseases to the population. Fleas from infected rodents are known to carry disease to human hosts. The Nile River, even in early days, was a polluted health hazard that became a breeding ground for abundant parasites. The archaeological remains from one Jerusalem cesspit, dated circa 586 BCE, revealed large numbers of eggs from the intestinal parasites tapeworm and whipworm. Whipworm may be an indication of foods contaminated by contact with human excrement, either through fertilization with night soils or from poor personal hygiene after contact with waste. Tapeworm can be associated with the practice of irrigation using sewage or with undercooked and infected beef and pork.

—Adam Aja

of the workmen's community, may give an indication of toilets for the poorer classes. This wooden seat sported a central hole and could have been placed in any convenient location.

While it seems likely that organic waste was recycled to fertilize the fields, there is little direct evidence for the practice. The archaeological discovery of pottery sherds in cultivated land might suggest the deliberate use of collected household debris as fertilizer. The concentration of recognizable waste would diminish with increasing distance from the settlements. There are many historic and ethnographic examples for compost fertilizers utilizing animal dung, ash, human excrement (night soils), and urban-derived refuse. Pits, both inside and outside residences, may have been the most commonly used storage features used for creating compost, which could later be carted out to fields or smaller garden plots. Archaeological excavations of the residential areas of Ugarit, an ancient settlement (dating to ca. 1190–1180 BCE) located on the northeast coast of the Mediterranean, revealed that many of the houses were equipped

with a stone-lined pit. These were frequently discovered containing domestic waste, including excrement. It is likely that pits dug for a variety of purposes were reused to serve as simple disposal sites, which would allow residents to bury waste, thereby hiding it from view. The contents of these disposal pits could be burned periodically to deal with odor and insects or to reduce the bulk of the waste.

It is clear that the dried dung of herbivores (most commonly of cattle, sheep, or goat) was used as an alternative fuel source, especially in dry climates where wood fuel was scarce. Wet dung can be collected, made into dung cakes by mixing it with straw or additional vegetable waste, and left to dry in the sun. The straw would bind the moist dung, and it could then be formed into regular size and shape for storage and sale. In archaeological contexts, the presence of charred seeds in hearth fires may indicate the use of dung fuel. Seeds can pass through the digestive tract of animals completely undigested. Additional combustible domestic waste may have served as alternative fuels as well.

The Rise of Civilized Disease Pools—William H. McNeil's Thesis

With the rise of urban civilization and state-level societies came diseases and epidemics. While diseases and parasites have always coexisted with humans, the substantial stable human settlements that characterize the period 4000–1000

BCE provided ample opportunity for the development of what William H. McNeil has called civilized disease pools. Prior to the rise of cities, humans lived in small enough groups that diseases could not be supported indefinitely. Either all of the local human population would develop immunity to the disease, or the disease would kill the entire small community and subsequently its own hosts. Diseases need hosts to survive, so one of two situations is necessary for the perpetuation of the disease. There must be carriers who have the disease but suffer no ill effects from it, or there must be a large enough population base so that there is always someone around who has never had the disease. The growth of cities and the explosion of population worldwide provided the necessary demographic background for the development of stable diseases. These large stable population bases are what McNeil refers to when he uses the term "disease pool."

Other elements of urban life contributed to the growth of civilized disease pools. Certain subsistence practices associated with population growth can contribute to a rise in disease. Most problematic are practices that bring humans into closer and continual contact with animal populations. Humans share diseases with a large number of animal populations, including poultry, horses, pigs, sheep, cattle, dogs, and rats. Settled society typically involved the utilization of poultry, sheep, cattle, and pigs; the use of dogs and horses; and the appearance of rats within the community. In most cases, as city life became more developed, humans decreased the variety of animal types that they were dependent on and increased the size of individual herds of animals. If there are many of the same type of animal around, then there are a larger number of hosts for the diseases to pass through, providing a longer time frame for humans to contract those diseases.

Parasites were also a problem in these early urban centers and state-level societies. Poor sanitation in the cities and concomitant contact with human feces allowed intestinal parasites to thrive. Mobile societies, which do not remain in the same area for any length of time, are not as likely to contract parasites in this manner. Parasites thrive in shallow water, so communities

utilizing irrigation agriculture were particularly susceptible to parasites. Individuals wading through shallow irrigation canals were likely to pick up parasites and transmit them to their families at home.

Disease probably had a very important demographic influence on the ancient city. Given the low level of medical knowledge during this period, there would have been a higher level of fatal incidences of disease. Indeed, it is very likely that the population of ancient cities was not entirely stable. That is to say, due to the ravages of disease in an urban environment, cities would have constantly been losing more members than would have been added. Immigration from rural areas must have played an important role in keeping stable populations in urban areas.

Disease pools become entrenched in urban environments but move in waves out to rural areas. Contact between city and town enlarges the disease pool. While a rural area cannot sustain a disease for very long, the urban region acts as a hub for disease to reach other rural areas. McNeil theorizes that the growth of state-level civilization drastically increases the size of a disease pool. Increased security for travel as well as transportation infrastructure allows cities to stay in close contact. More contact between cities allows more opportunities for diseases to develop and transfer and hence a larger disease pool.

For McNeil, these state-level disease pools played an important role in the long-term success of larger states over smaller states and regional polities. When ancient societies came into contact with one another, those with larger disease pools brought with them a biological weapon of sorts. The smaller societies would have succumbed not only to the greater military strength of an aggressive larger society but also to the higher number of virulent diseases to which the larger society had developed immunity.

Unfortunately, the study of ancient disease and epidemics is constrained by a lack of sources. Ancient scholars did not well understand disease and parasites, nor did they understand infection and immunity. So we have very few records that directly attest to pandemics or epidemics before the Classical era. Scholars are confined to the analysis of human remains or to reading between the lines of ancient historical

➤ IDENTIFYING DISEASE ARCHAEOLOGICALLY

Disease is not easy to identify for the period 4000–1000 BCE. The best direct evidence comes from the investigation of human remains recovered archaeologically. Human remains are preserved to different degrees depending on a number of factors, especially the environment. Most remains from this period are simply the bones of the dead, which have only limited use in identifying ancient diseases. However, if the disease was of a type that eroded away bone structure, caused growths on the bones, or affected the bone structure itself, then these diseases may be identifiable. Leprosy and polio are probably the most readily visible diseases archaeologically.

If any soft tissue has been preserved, then it is much more likely that paleopathologists will be able to identify an ancient disease. Parasites may actually be preserved in the soft tissue and be identifiable to the specialist. Viruses leave visible traces in the soft tissue and may also be recognizable. Perhaps the most affective approach is through DNA analysis, where the genetic traces of ancient diseases can be identified in preserved specimens.

Demography in Ancient Societies

The word “demography” brings to mind ideas such as census and population size, in short how many people and where. But besides counting heads, the study of demographic processes in ancient societies is relevant for the understanding of their social and political configurations as well as of their economies. Much of what archaeologists have done in this sense has to do with questions such as: What explains a certain demographic transition? Why do people have large families in some times and places and small ones in others? Why do preferences of family or

➤ HAS POPULATION GROWTH BEEN INEVITABLE THROUGHOUT HUMAN HISTORY?

Interpretations of demographic processes are often infused with the idea of the inevitability of population growth, when in fact this does not seem to always be the case. Several political dynamics in antiquity, such as warfare, imperialism, or the very emergence of social complexity, have been argued to be the result of a growing population that eventually could lead to a shortage of resources. However, small bands of hunter-gatherers (which represent the most frequently employed lifestyle during the vast majority of human history) employed several kinds of methods of population control in order to limit population size. When resources were abundant (relative to population size) and time could be devoted to the development of technology, humans frequently attempted to live with a smaller population. Thus, when reconstructing the demography of ancient societies, assuming a necessary relationship between resource abundance, technology, and population growth (and not assuming that population growth is inevitable) will yield more accurate results.

—Andrea M. Cuéllar

community size change? Why have regulations about family size emerged? Other questions related to demographic processes that relate to settlement organization are: Why do people settle in a compact fashion or in a dispersed one? Is life in compact communities inherent to our social nature? If so, why have so many people preferred to live in a dispersed fashion throughout human history? Why did urban centers emerge in some places but not in others?

Of course, the first step toward answering these interesting questions is demographic reconstruction (how many people, when, and where). Archaeologists deal with a material record that is often extremely fragmented and hard to interpret, but this does not deter them from reconstructing demographic histories based on demographic approximations, as a real and total census of a nonexistent population is not within their reach (or the reach of contemporary de-

mographers for that matter). These demographic approximations can be based on absolute estimates: “the population of Ticoman phase Cuicuilco was about 7,500 people” or “rural family size in Moundville was six people.” These approximations can also be relative: “Classic period Maya population at Palenque was *larger* than at Tikal” or “the size of residential groups *increased* from Middle to Late Horizon in the Andes.”

To get to these approximations, absolute or relative, archaeologists look at a variety of evidence. If bone is well preserved and the funerary customs are known, archaeologists can count individuals at cemeteries or household graves. Alternatively, they can measure house floor area and estimate the number of people per house. They can also use areas of occupation, measured by the dispersion of refuse, as a proxy for population. Only in a few cases can archaeologists use written records that contain census data or even maps that had often been produced by imperial authorities. These have sometimes been compared to archaeological data and have been useful in helping to calibrate the tools with which archaeologists estimate ancient populations.

Once archaeologists marshal this kind of information, they can start to answer the interesting questions laid out above. The theoretical frameworks that are typically used to interpret demographic information usually emphasize the economic determinants of demographic processes. Thus, most of our understanding of demographic histories revolves around variations of the relationship between people and resources (be it at the family level or at much larger scales). For example, fertility decline and the replacement of large families by small families have been linked to the advent of technologies or labor configurations that promote the economic autonomy of individuals. This would seem to make logical sense, but it is based on an instrumental view of the family (as if this was simply a function of economic processes).

Although the relationship between some demographic and economic dynamics is undeniable, never in human history has this association occurred outside of a cultural context that gives meaning and shapes demographic processes. It

is with this basic premise in mind that demography in ancient societies is more productively studied. Small or large family size, dispersed or compact community, and urban or rural are all part of cultural ideals and have been experienced as such throughout human history despite the fact that political or economic forces are intertwined with them.

■ Introduction: Religion and the Environment

When one first studies ancient religion, it is tempting to try to equate various ancient gods with various natural phenomena. For example, students of ancient Egypt may begin by trying to identify the various "sun gods" in that ancient religious system. Likewise, students of mythology are often tempted to see myths as means of explaining the natural world. These myths are often looked upon with a sort of superior scorn, with the implication that these ancient people lacked the benefits of modern science to really understand their environment. Scholars of ancient religion try to avoid these sorts of overly simplistic approaches, recognizing that ancient spiritual beliefs were much more complex than these sentiments imply.

Still, religious beliefs and myths did play an important role in mediating (and understanding) the human relationship to the environment. While it is best not to think of ancient deities as equating directly with weather phenomena, some gods were thought to control elements of the climate or were associated with various astronomical bodies (especially the sun, moon, and Venus). Many myths did, in part, explain the origins of weather events. In other instances, mythological language was used as a means of expressing observations about the environment.

What follows are some noteworthy examples of the intersection between religion and the environment in the period from 4000 BCE to 1000 BCE.

—Kevin M. McGeough

Egyptian Solar Deities

The sun was omnipresent in Egyptian religion and daily life, an importance made all the more conspicuous by the sun's nightly disappearance. Consequently, no other aspect of divinity in ancient Egypt was more widely recognized and worshipped than the sun god. As the single most important manifestation of the primordial creator, the sun was understood as the source of time (*neheb*), the guarantor and prime recipient of cosmic order (*ma'at*), the regulator of the seasons, and the source of life itself, both in this world and the next. In addition, the sun was thought to be the wellspring of kingship, and from the Fourth Dynasty (ca. 2649–2513 BCE) onward, Egyptian kings took the epithet "son of (the sun god) Re" (*za Ra*) as an explicit indicator of their divine pedigree.

The Egyptians recognized many different aspects of the sun. The basic term for the sun itself was Re (probably pronounced something like "*Ri'a*"). Since Re's daily progress from east to

west appeared to entail a cyclical waxing and waning of the disc's light, the Egyptians developed a biological mythology of aging to explain this phenomenon. Each morning, the sky goddess Nut was said to give birth to the newborn sun, identified as the scarab Khepri ("he who becomes"). The solar child then evolved into his mature form as Re, typically shown in the guise of a falcon-headed male and representing the sun at midday in the height of his power. After this, the sun assumed the form of a feeble old man identified as Atum ("he who is finished/complete") with the head of a ram. Nut then swallowed the aged sun god into the western horizon, passing him through her body, in order to bring light and temporary revivification to the dead. At the midpoint of the sun's nocturnal journey, he would unite with the corpse of Osiris, god of the dead. The temporary union of these two deities enabled the sun to reverse the aging process and once again assume the form of the solar child, to be reborn from his mother's thighs in the eastern horizon the next morning. This solar journey through day and night was mapped out in great detail, according to two 12-hour cycles, from which our own 24-hour day derives.

In addition to the triple god Khepri-Re-Atum, the Egyptians also recognized the disc of the sun as the physical vehicle of the deity. The term for this disc, *aten*, is attested from the earliest religious texts but only began to acquire special status as a god in its own right in the Eighteenth Dynasty (after ca. 1500 BCE). The deification of the *aten* reached its height during the alleged heresy of King Akhenaten (ca. 1372–1355 BCE), who sought to give preeminence to the visible aspect of the solar disc while excluding the nocturnal realm of Osiris and many traditional aspects of pluralistic divinity.

Almost any god or goddess could acquire significance as a solar deity. Thus, the goddesses Hathor and Sakhmet were viewed as twin aspects of the fiery eye of Re, the sun as a destroyer who withers crops and burns flesh with the potential to destroy all life. Conversely, the feline goddess Bast eventually assumed the role of the benevolent sun, whose light and warmth nourish all living things. One of the great reli-

gious compositions of the New Kingdom, the Litany of Re, exemplifies this desire to quantify and describe the various forms of the solar deity. This text describes the 74 aspects of the sun god as part of a ritual whose focus is the union of Re and Osiris, ostensibly for the benefit of the king. In describing the sun as a multifaceted god by whose nature the cosmos, life, and death are made manifest, the litany constructs a hermeneutic theory of solar divinity, which provides an unparalleled degree of insight into the nature of an ancient god.

Communicating the Environment in Egyptian Art

Life in ancient Egypt revolved around the Nile River. The day-to-day realities of life in the river valley therefore played a huge role in the formulation of Egyptian religious thought and the expression of its concepts in tangible form, expressions that later civilizations have come to identify as works of art. The Nile cuts a swath of fertile land some 750 miles (approximately 1,200 kilometers) in length, from the first cataract south of Aswan to the tip of the Nile Delta, which begins approximately 13 miles (20 kilometers) north of present-day Cairo. Along the edges of this valley, great cliffs separate the low-lying tract of the river from the plateau of the high desert beyond. The soil of the valley, fertilized by the annual inundation, assumes a rich,

black color that stands in stark contrast to the arid red soil of the desert. The black soil came to be identified with Egypt itself, dubbed Kemet (Black Land), while *desbret*, the red desert, was associated with the destructive forces of chaos. Above the valley, the sun could be observed in its travels from east to west, marking the progress of the hours and the change of the seasons. This cyclical rising and setting served as a constant reminder of the delicate natural balance and fundamental order, or *ma'at*, upon which all life in Egypt depended.

Egyptian art possessed a vast repertoire of images used to depict various aspects of riverine existence. The bounty of the Nile itself could be personified as the androgynous god Hapy, who was typically shown as a corpulent man carrying armloads of agricultural surplus. Images of fishing and fowling from private tombs depict nonroyal Egyptians engaged in the act of hunting native marsh wildlife with throw sticks, nets, and trained cats. Subtle iconographic clues indicate that such representations were intended to show the deceased symbolically reigning in the forces of chaos. The hunter's posture mimics the smiting pose assumed by the king as he crushes the skulls of Egypt's enemies, allowing the private individual to participate, in some small measure, in the maintenance of cosmic order. The vast papyrus marshlands in which these hunts took place were represented as a paradisiacal land of plenty known as the Field of Reeds, or *sekbet ialu*, that eventually found its way into Greek as Elysium, the Isle of Blessed where the righteous take their repose.

So-called scenes of daily life from tombs of the Old Kingdom (ca. 2650–2150 BCE) are replete with images illustrating the interaction of the ancient Egyptian with his environment. These scenes shed light on practices as diverse as river navigation, the avoidance of dangerous creatures such as hippopotami and crocodiles, cattle herding, animal husbandry, and agriculture. The fact that such scenes figured so prominently in the decoration of private tombs amply demonstrates the Egyptians' perception of their role as masters of their environment and the importance placed on these activities even after death.

➤ THE HORIZON AS HIEROGLYPH

Massive pylons front the Temple of Edfu, Egypt. (Bernt Rostad)

The physical geography of the Nile Valley—a central lowland flanked by cliffs to the east and west with the sun overhead—was expressed in the hieroglyphic script as . This stylized horizon, or *akhet*, eventually crept into virtually every aspect of royal and private art and architecture. The most striking example of this phenomenon can be seen in the structure of the great pylons—massive gateways consisting of paired, sloping towers joined by a central doorway—that fronted the entrance to virtually every major Egyptian temple. The same concept can be observed in two-dimensional representations as far back as the Old Kingdom, which depict a horizontal strip of land flanked by two human heads personifying the eastern and western mountains of the horizon. This symbolic Earth would then serve as the lower register line for the text and images above it, with a hieroglyphic representation of the sky (Egyptian, *pet*)  placed above it. The area bounded by these two signs symbolically re-created the physical environment of Egypt as a microcosm, or world in miniature. Related images of the horizon appear again and again in both two- and three-dimensional art from all periods. Virtually any image consisting of two symmetrical halves could be interpreted, on some level, as an expression of the horizon, constantly evoking the regenerative power of the solar cycle.

Baal, Ugarit, and Rainstorms

The ancient urban center of Ugarit (Tell Ras Shamra), located approximately half a mile (one kilometer) off the coast of the Mediterranean Sea on the Syrian coast, was an important city-state that flourished in the second half of the second millennium BCE. As the capital city of a small kingdom of the same name, Ugarit was occupied as early as the Neolithic Age (seventh millennium BCE) and abandoned around 1180 BCE, though the site was minimally occupied at later times. Of special interest to historians of the ancient Near East and the Bible, in 1928 CE a large cache of texts was discovered in Ugarit's ruins, revealing a previously unknown language—Ugaritic—and thousands of clay texts written in alphabetic cuneiform on topics ranging from receipts to personal letters to mythological literature. This literature, revealing a realm of western Semitic gods and heroes, sheds light on Ugaritic religion and mythology that often serves as an important point of comparison for many of the religious practices and worldviews described in the Bible.

At its height (fifteenth through thirteenth centuries BCE), the small kingdom of Ugarit encompassed hundreds of tiny villages and towns and covered an area of approximately 772 square miles (2,000 square kilometers). Ugarit's approximate borders were the coastal mountain Jebel al-Aqra (its ancient name was Mt. Sapanu) in the north, the Orontes River in the east, and the area of Jebel in the south. The city itself was situated on a plain bordered by two small streams (Nahr Habayyeb on its north and Nahr ed-Delbe on its south), .6 mile (1 kilometer) east of a natural harbor (Minet el-Beida) that served as Ugarit's seaport. Public buildings, such as the three royal residences, and the houses of the high officials were situated in the western half of the city. The

eastern half of the city contained an acropolis, a temple for Baal, a temple for the god Dagan, and the residence of the chief priest. Additionally, several private houses have been excavated throughout the city, revealing homes occupied and utilized by artisans, officials, and scribes.

The economy of Ugarit, which is situated on the north-south coastal highway and acts as the western terminus for the highway that connected northern Syria and Mesopotamia to the Mediterranean Sea, was based primarily on maritime trade and flourished especially during the Late Bronze Age (fifteenth through thirteenth centuries BCE). Ugarit was economically strong but militarily weak, often affiliating with stronger foreign military powers, first the Egyptians (before ca. 1330) and then the Hittites (after ca. 1330). Often described as cosmopolitan, Ugarit reveals the influence of many surrounding cultures: in its material culture, pottery from both Cyprus and Mycenae were imported; in its written materials, at least seven languages have been attested in texts found at Ugarit; and in evidence that Egyptians, Hittites, and Hurrians were known to have lived in Ugarit.

At the beginning of the twelfth century, with the ability of the Hittite empire to protect Ugarit waning, the city came under attack from the sea with increasing frequency. Ultimately, the city was destroyed, with traces of fire, arrowheads, and buried objects remaining in the ruins. The city of Ugarit was not repopulated for nearly 1,000 years.

The most important deity in Ugarit was Baal, a Canaanite warrior-god of storms and fertility. Baal is an epithet meaning "lord" and refers to a god named Hadad, meaning "thunderer." Known primarily from Ugaritic texts and the Bible, Baal is also attested in texts from Ebla, Egypt, and in Phoenician inscriptions. This deity was also known by several descriptive titles such as Òvictor Baal, "rider of the clouds," "mightiest of the heroes," and "the prince lord of the earth." In these titles can be seen references to Baal's role, attested throughout the Ugaritic literature, as hero, storm-god, and king.

Baal is known both as the "son of Dagan" and the "son of El." The latter of these is not likely to indicate the conception of a genetic relationship between Baal and El but rather that

Baal was a divine being under the figurative fatherhood of El as the head of the Ugaritic pantheon of gods, virtually all deities in Ugaritic mythology being “brothers and sisters,” “sons and daughters of El.” Baal was often affiliated with the goddess Anath, his primary consort. Occasionally another goddess, Astarte, serves as Baal’s consort, though why Baal has two different consorts is never entirely clear.

Though known from many Ugaritic texts, Baal is most centrally featured in a six-tablet series of texts known as the Baal Cycle. In this narrative, Baal conquers Yam (“Sea”), seeks and obtains permission from El to build his new royal residence on Mt. Sapanu, and battles with Mot (“Death”). These three narrative elements are united by the main theme of kingship as Baal performs kingly duties, conquering the chaotic elements of Sea and Death and establishing his own palace. In the Baal Cycle and other Ugaritic texts, Baal is depicted as a warrior-god of the storm whose voice thunders, who rides on the clouds, who battles against chaos, who causes nature to convulse at his appearance, and who fertilizes the earth through storms. Though Baal fertilizes the earth through rainstorms, human fertility does not typically appear to be within Baal’s purview, though in the story of Aqhat, Baal does entreat El, on behalf of the human Aqhat, to grant a son to Aqhat.

Within the biblical text, Baal is frequently depicted as the object of worship for Israelites who have gone astray after other gods. Still seen as a storm-god (1 Kings 19), Baal is frequently associated with Asherah, who is typically the consort of El in the Ugaritic literature. It appears that the pairing of Baal with Asherah may be part of the biblical writers’ polemic against non-Yahwistic religion.

Mesopotamian Astral Deities

The stars and visible planets played an important role in Mesopotamian religion and daily life. The heavens and the celestial bodies within them were consulted by diviners seeking clues to future events, invoked by exorcists or witches to help their patients or harm their victims, studied by those seeking propitious moments to gather herbs or prepare medications or amulets, and appealed to by those seeking protection against various misfortunes or help contacting the gods. Given their significance and the energy devoted to studying the stars, it is unsurprising that some of the most prominent deities of the Mesopotamian pantheon had astral manifestations in addition to their other roles. Those gods who lacked specific affiliation with the stars or planets were often associated with other important features or phenomena of the natural world.

The three most important of the astral gods and goddesses were Sin, Shamash, and Ishtar. Sin, known as Nanna in Sumerian, was the moon god. As the Mesopotamian calendar was based on the lunar cycle, he was especially important for determining the proper date on which to perform specific rites and rituals. Often represented by a crescent moon, he was also depicted in anthropomorphic form with a distinctive

► THE BEARDED ISHTAR

The identification of Ishtar with the planet Venus may explain the occasional descriptions or renderings of the distinctly female goddess with a beard. While it was recognized that Venus appeared twice during the day, the two manifestations were assigned to different genders. The planet was typically considered female in the morning and male in the evening, although these attributions could be reversed. Venus's dual nature has been paralleled with Ishtar's feminine role as a goddess of love, albeit primarily sexual, and her more masculine role as a patron of war. Other explanations for Ishtar's masculine qualities have been put forth, however, including her connection to Athtar, a male god of South Arabia.

—Karen Sonik

crescent headdress or with rays emanating from his body. Shamash, called Utu in Sumerian, was the sun god. In the course of his daily journey across the sky, he not only offered light and warmth but also witnessed all manner of good and evil deeds performed by humans. This led to his role as the god of truth and justice as well as to his patronage of some of the great heroes of Mesopotamian myth, such as Gilgamesh and Etana. He was often represented by a solar disk or was depicted, like Sin, as an anthropomorphic deity with solar rays. Ishtar, identified with the Sumerian Inana, was the goddess of sexual love and war and took the planet Venus as one of her aspects. Frequently represented by the eight-pointed star in later representations, Ishtar's anthropomorphic representations varied depending on which aspect was being emphasized by the artist. She was often depicted as a clothed female with weapons sprouting from her shoulders, signifying her warlike nature, but could also be shown nude, stressing her sexual character, or with a beard, indicating her masculine qualities.

Other deities with astral associations included Nergal, an underworld god responsible for plague and disease who was identified with the inauspicious planet of Mars; Ninurta, a warrior and farmer god connected to Sirius; Nabû, a scribal god likely identified with Mercury; and

Gula, a goddess of healing associated with Capella, the Goat Star. In addition to the stars and planets with which these gods were associated, other celestial bodies and constellations were invoked in various prayers, incantations, and rituals. While the reason that a specific astral deity was appealed to in a particular situation was rarely recorded, there are occasional cases where it may be deduced. Thus, lovers seeking to kindle or rekindle affections frequently called upon Venus, and those seeking to heal or be healed often left the medications they had prepared out in the light of Capella.

Environment and the Vedas

Although their main focus is religious, the Vedas contain some geographical and environmental information about the lands inhabited by the early Indo-Aryan people and the shift through time in their geographical horizons. The Vedas were composed over a long period: the Rig-Veda probably between 1500 and 1000 BCE, the others slightly later. During these centuries archaeological evidence shows a shift in settlement from the Punjab into the Ganges Valley and major economic and political changes. The authors of the Vedic *sambitas* and the people whose religious life they reflect were part of this eastward movement, as were the descendants of the Harappans and other native communities and probably also non-Vedic Indo-Aryan-speaking groups. There are also hints in the earliest parts

of the Rig-Veda of life before the Vedic people began to settle in the subcontinent. River names and geographical interrelations may indicate that early Indo-Aryans were among groups who migrated to Seistan during the early centuries of the second millennium BCE.

By about 1500 BCE, Vedic Indo-Aryans were moving into South Asia, where they applied old names to the new rivers they encountered. The earliest parts of the Rig-Veda reflect this initial period in the northwest, with many references to mountainous country and mountain passes. Rivers identifiable as tributaries of the Indus, including the Kubha (Kabul), Suvastu (Swat), Krumu (Kurrum), Sushoma (Soan), and Gomati (Gomal), show familiarity with the upper Indus region; northernmost is the Rasa, a possibly mythical stream high in the Himalayas (known as Himavant). The Yavyavati may be the Zhob in southern Baluchistan; otherwise, their southern limit may be the Bolan Pass, inhabited by the Bhalanas tribe.

Most of the Rig-Veda reflects settlement in the Punjab and lands as far as the Yamuna, an environment containing extensive scrubland and pasture but also forests yielding fruit and game. Regions to the south are described as forested and inhabited by indigenous tribes. The Punjab is known as the Sapta Sindhavah (Seven Rivers): the Sindhu ("river" in general but here applied specifically to the Indus), Vitasta (Jhelum), Asikni (Chenab), Parushni (Ravi), Vipash (Beas), Shutudri (Sutlej), and Saraswati.

The river that today bears the name Saraswati (Sarsuti) is one of a number of small seasonal rivers that rise in the Siwaliks; these also include the Chautang (probably the Vedic Dri-shadvati). However, Vedic hymns describe the Saraswati as a major river, flowing to the *samudra* (usually translated as "sea," although it literally means "gatherer of waters"). Surveys in the region have revealed that the Saraswati and Chautang, along with the now largely dry Ghaggar-Hakra river channels, once formed a major river system, fed not only by the small rivers of the Siwaliks but also by the Sutlej, which flowed into the Saraswati, while the Himalayan river that now feeds the Yamuna at that time flowed into the Chautang. The lower course of this system is still uncertain; it may have reached the

sea but more probably ended in a major inland delta in the Thar Desert in Bahawalpur.

At some time in the past, tectonic activity in the Himalayas caused the eastern river to change its course and flow into the Yamuna, and some time later the Sutlej was captured by the Indus system. Thus, the Saraswati system lost its main sources of water. Archaeological evidence of settlement along paleochannels shows that the rivers of the Saraswati system were in full flow in the third millennium BCE and that the decline took place mainly during the second millennium, the time when the Vedic people were moving into this region.

It is difficult to match the magnificent river described in the Rig-Veda with the Saraswati as it would have been in Vedic times. It therefore seems possible that the river originally described in this way was the Arghandhab-Helmand in Seistan. This has been identified as the Harakhvatti, the Avestan river whose name is equivalent to Saraswati; it is a major river and flows into a vast inland lake, the Hamun-i Helmand. Later, as the Vedic people moved east, they applied the name "Saraswati" to other less suitable rivers (at least seven rivers of this name are known in India) while preserving the memory of the original Saraswati.

The Ganges is mentioned only once in the Rig-Veda but appears more often in the later Vedic texts. The Atharvaveda in particular refers to regions as far east as Angra (West Bengal). By this time the Saraswati and Yamuna appear as the principal rivers; others include the Gomati (Gumti) and Sarayu (Sarju, Gogra) in the Ganges basin, both of them names transferred from rivers farther west. What had in Rigvedic times been the extreme southeast of known territory was by now the central Indo-Aryan region, the Middle Land (Madyadesha), of which the most important region was Kurukshetra (the lands around the upper Saraswati, referred to in Rig-Veda III.53.11 as "the earth's choicest place"). Western regions are still mentioned in Atharvaveda, including west-flowing rivers and the Sapta Sindhavah, where a strong north (winter) wind is said to blow. The Himalayas are described as a mountain region toward which clouds float, where it rains at all times of the year. In the warmer eastern region beyond the Middle Land

► THE ENVIRONMENT IN VEDIC IMAGERY

The natural world played a major role in Vedic religion, so there are frequent descriptions of natural phenomena in the Vedic texts. Although some are realistic, others relate more to imagined features of the idealized and superlative realm of the gods than to their pale reflection observed on earth. This may be the case with the magnificent divine river Saraswati. The Vedic hymns are rich in imagery, drawn from the natural and human worlds. For example, the Maruts, the gods of the winds, are portrayed as warriors, hurling boulders in competition, driving their chariots, and releasing rain as from a skin container (Rig-Veda I.85). The mighty Sindhu River is described as “bellowing like a bull,” like a warrior leader marshalling his troops, leading the “roaring rivers” that run into it like cows rushing to their calves. Its own waters are “flashing and whitely-gleaming,” “magnificent and unrestrained”; it is “rich in steeds” and “rich in gold” (Rig-Veda X.75). Another hymn (Rig-Veda 1.92) describes the stages of dawn breaking: the first light appearing like cattle coming out from of their pen, a flame driving back the monstrous darkness, its rays spreading like a river in flood, like banners across the sky; Dawn’s beautiful smiling face gazing everywhere and bringing every living thing awake.

—Jane R. McIntosh

grain ripened earlier, while farther west there was desert. By the time of the *Brahmanas* the whole of northern and central India was known territory. The easterly regions are described as heavily populated and rich in cattle and goats, while regions farther west are described unfavorably as wilderness, useful for grazing and fruit but not suitable for agriculture, and as lands with hail and harsh winters. Farther north are “hungry” lands that lack rain but where horses and woolly sheep flourish, along with camels. People recognized in the texts as Aryans are now divided into Amavasava (those who remained “at home” in the northwest) and Ayava (those who moved east). There are now references to seven rivers flowing east: the Yamuna and Ganges and their tributaries. The river Sadanira forms the boundary between the Middle Land and the ter-

ritory of the Kosalas and Videhas, the easternmost Indo-Aryan groups at this time. Their lands are initially described as marshy and uncultivated but were used for agriculture by the Brahmana period.

By now the Saraswati and Drishadvati had dried up significantly so that there was no longer water in the Ghaggar-Hakra, and the rivers themselves were said to disappear into the ground at Vinashana and Triplaksh, making the abundant waters of the Yamuna and Ganges significantly more attractive. The far more heavily forested environment of the Ganges basin was cleared for cultivation using both fire and iron tools. Reference to plow teams of 6 or 8 and even 12 oxen reflect the heavy work of land preparation, which in the case of newly broken ground would include ripping out tree stumps.

By the time of the latest Vedic texts, in the later first millennium BCE, much of the subcontinent was known territory. Geographical references to areas outside the Vedic core, however, are rare, since they were of little interest to orthodox Brahmins.

Yu, Tamer of the Waters, and Other Chinese Tales of Environmental Power

Yu is one of several great cultural heroes of China’s mythic past. Whether understood as heroes who became venerated as gods or gods who came to be understood as model rulers in Chinese history, the tales of the contributions of these heroes reflect advances of Chinese civilization. Environmental power is central to many myths. For example, the Three Sovereigns include Fuxi (Fu-shi), who is recognized for inventing hunting, fishing, and domesticating animals,

➤ SHENNONG, CULTURAL HERO OF AGRICULTURE

Yu's contributions of taming the floods and carving out an effective system for irrigation built upon the agricultural advances attributed to Shennong (Shen-nung). Chinese mythology describes Shennong, the "Divine Farmer," as a god of agriculture and medicine. Traditional Chinese history places him in the twenty-eighth century BCE as one of the Three Sovereigns (San huang). He is understood to have invented the plough and taught the people of China how to cultivate food. He is also associated with the burning wind, which suggests that his creation of a plough may represent advancing beyond slash-and-burn agriculture. Appreciation for Shennong's contributions included worship during the imperial spring plowing ceremony, which signaled the annual start of the growing season. His close association with plants extended to skill in their medicinal uses, and thus he is known as the father of Chinese pharmacology. Shennong's transparent stomach allowed him to develop extraordinary knowledge of the medicinal power of plants by observing their interaction with his body. As the cultural hero attributed with inventing agriculture, Shennong's mythic contributions were pivotal to the development of Chinese civilization and serve as the origin of farming, which remains the most widespread occupation in China even today.

—John Harding

Shennong. Funeral stone carving of Eastern Han dynasty (25 CE–220 CE), Wuliang Shrine, Jiaxiang County, Shandong Province. The inscription reads, "Shennongshi taught people to cultivate according to the land's quality and to sow grains in order to relieve the hungry people." A popular culture hero who started agriculture, Chinese medicine, the market, the Zhaji Sacrificial Rite, and also invented many farm tools and musical instruments. (Feng Yunpeng and Feng Yunyuan, Research on Stone Carving, 1821. Reprinted Shanghai: Shangwu Yinshuguan, 1934)

and Shennong (Shen-nung), who is known as the "Divine Farmer" for inventing agriculture. Chinese history places Huangdi (Huang-ti), the "Yellow Emperor," just after these two in the twenty-seventh century BCE and credits him with numerous cultural advances such as writing, boats, and silk cloth. He is listed as the first of the Five Emperors leading up to Yu, whose reign is traditionally dated to the twenty-second century BCE. Similar to these cultural heroes who preceded him, Yu's origins and exploits include extraordinary powers and associations

with nature. Rather than a tale of human separation from and defeat of nature, Yu's story maintains that he was so integrally tied to nature that he could take on the form of a bear and read nature's signs. He is described as a shaman in stories that maintain that his father, Gun (Kun), and the emperors Yao and Shun, who ordered him to tame the floods, were also shamans as well as shape shifters.

Yao is described as a model ruler who recognized that something must be done to combat the floods of the Yellow River. Yao, or his successor

Shun, assigned Yu's father, Gun, to tame the floods. Gun worked at this task for years and built dams and dikes in an attempt to contain the waters. However, his method failed to control the floods. The *Classic of History (Shujing)*, an influential Zhou source that includes myths of the Three Sages—Yao, Shun, and Yu—implies that Gun partially succeeded in damming the flood but thereby created more chaos and was executed as a punishment. Gun's body was left exposed to the elements for three years, but then in an extraordinary turn of events he was revived and took on the form of a bear, splitting open his belly and extracting his son, Yu. Other versions maintain that after three years Yu, in the form of a dragon, was extracted from his father, who then turned into a bear. Either way, Yu bears all the marks of a cultural hero from his miraculous birth to his great exploits and sage rule. He inherited the ability to become a bear, and he surpassed his father by taming the floods through an environmental transformation that yielded a more orderly system of rivers that irrigated the land for agriculture and flowed out to the sea. While Yu's father had been slain and abandoned for failure, Shun rewarded Yu's hard work and impressive success by ceding power to him.

Mythic accounts of Yu's feats maintain that he transformed the landscape through 13 years of hard labor. Yu is reported to have continued his shape shifting as he roamed across the country building up mountains above the flood plain, bolstering the banks of rivers and lakes, breaking through mountains and rocks to release trapped waters, draining marshes, and carving channels to redirect the water's flow. Yu's ability stemmed from his close connection with nature and the cooperation of other powers, which according to some accounts provided him with a book to gain mastery over the waters. Legends claim that he traveled to the stars to learn from spirits in that realm. His work created rivers and other waterways that simultaneously tamed the floodwaters, redirected water to cultivate the land, and connected the country. The altered landscape of a more orderly and unified China came to be described in divisions of nine radiating out from the basic irrigation design, where intersecting pairs of parallel channels of water divided arable

land into nine sections in a tic-tac-toe grid pattern to corresponding references in Classical literature such as "How did he set bounds to the Nine Lands?" in the "Heavenly Questions" verses of *Songs of the South* or the "Great Norm with Its Nine Categories" in the *Classic of History*.

Yu's story may have been used to emphasize the importance of environmental powers, such as rivers, in cultivating or destroying crops through irrigation and flooding, respectively. It may have also served to explain environmental changes such as actual shifts in the course of the Yellow River—two major course alterations have been dated to the middle and the end of the third millennium BCE—to cultural shifts away from more primitive techniques of agriculture and water control, symbolized by Gun's attempts, to the large-scale irrigation attributed to Yu. Stories of Yu also continued to influence shamanic practice, as later shamans donned bearskins and attempted to retrace through dance Yu's bearlike gait and celestial journeys.

Legends of Yu link him to nature from shape shifting to forms of a dragon and a bear to shaping the landscape and its cultivation. He is linked to Chinese civilization, culture, and governance more broadly, as his extraordinary abilities, attunement with nature, hard work, and success in taming and redirecting the waters to provide for survival and the unity of the country were rewarded with rule. Myths of Yu and his son link them to Chinese dynastic history. Yu's wife is said to have turned to stone in fright or exhaustion upon fleeing from him in the form of a bear. Whereas he would typically beat a drum to signal his wife to bring food, that day he was still in the shape of a bear when his wife mistook the sounds of his work for the beating of the drum. His son, Qi, was extracted from his wife's stone belly, echoing his own birth story. While Yao and Shun are venerated for passing over their sons and choosing successors based on merit, Yu reluctantly broke precedent when Qi succeeded him as ruler. This departure is explained as being in keeping with the will of the people and ministers who wanted Yu's son to rule. This hereditary succession designated Yu as the virtuous founder of the Xia (Hsia) dynasty, the first dynasty in traditional accounts of Chinese history. The existence of the Xia and Shang Dynasties

was challenged with the introduction of more critical scholarly methods of historical verification in the early twentieth century. However, extensive archaeological discoveries in the 1920s have firmly established the existence of the Shang dynasty. While the Xia dynasty remains in doubt, there is a growing body of evidence that may prove its historical validity, although perhaps as one of many regional states that coincided with rather than preceded the Shang dynasty.

Mesoamerican Sacrifice and Earth Fertility

Human sacrifice and bloodletting (autosacrifice) were Pan-Mesoamerican religious rituals found across time and space in the civilizations of the region whether Olmec, Teotihuacan, Maya, Mixtec, Zapotec, or Aztec. These rituals were intertwined with religious belief in universal cycles of gods sacrificing to create and nurture humans and the human need to do the same for the complex Mesoamerican pantheon of deities. While we know much about these rituals after 1000 BCE from archaeological and written sources, they likely have their origins in the period 4000–1000 BCE when sedentary agricultural societies first emerge with early Olmec and proto-Maya civilizations.

The lack of domesticatable animals led Mesoamerican civilizations to rely heavily on domesticatable plants such as maize and thus on their ecological ties to Mother Earth for sustenance. Blood sacrifice became associated with earth fertility, especially the life cycle of corn. Acquisition of captives for sacrifice, often through warfare, and elite shamanistic and family autosacrifice

Mayan lintel shows a blood offering made by Xoc, wife of the Mayan ruler Shield Jaguar. Xoc is shown kneeling and drawing a thorny cord through her tongue. Accession ritual from Structure 23, lintel 24 at the Mayan site Yaxchilan in present-day Chiapas, Mexico, about 725 CE. (Bettmann/Corbis)

helped maintain the cosmic balance necessary in all aspects of life including earth fertility, city planning, and state politics.

Archaeological evidence in the form of imagery, artifacts, and burials points to shamanistic origins for blood sacrifice in Mesoamerica. Bloodletting artifacts such as stingray spines and sacrificial burials have been found at the local village levels associated with droughts and wells. Sacrifices might have occurred in small groups and included all age sets. By 1000 BCE at sites such as San Lorenzo for the Olmec and later Cuello for the Maya, blood sacrifice had been institutionalized in Mesoamerican civilizations. Some of the earliest examples of writing have sacrifice as a theme to keep the cosmic vital force in balance. The Maya called this force *ik*, the Zapotecs *pee*, the Mixtec *ini*, and the Aztecs *tona*. Later-

constructed creation myths of the Maya based on the Popol Vuh and the Dresden Codex probably echoed these early beliefs.

The Maya Hero Twins story exemplifies this. Hunapu (sky, sun, life) and Xbalanque (underworld, death, Venus) travel to the underworld of Xibalba, entered via caves and ball courts, to outsmart the lords of death. They intentionally sacrifice themselves and trick the gods into bringing their ground-up bones back to life. The gods then wish to learn this secret and have the twins sacrifice them. However, the twins do not bring the gods of death back to life and instead negotiate a deal whereby human blood can be used to rebirth the universe, the sun, the rain, the gods, and the corn of Mother Earth. The Maya god Bulac Chabtan is the god of sacrifice,

and the Hero Twins are also known as the Twin Corn gods, further solidifying the ties between sacrifice and earth fertility.

Society and Culture

Human sacrifice seems to have occurred irregularly in the period from 4000 to 1000 BCE, from China to Europe, from Mesopotamia to Egypt. One of the most grisly (but at the same time compelling) finds in archaeology was the Great Death Pit of the city of Ur in Mesopotamia. The Great Death Pit, along with other graves, preserved the remains of numerous people who had been sacrificed within the tombs of dead royalty. No one knows how the individuals who were killed to accompany the kings and queens of Ur must have felt about their sacrifice. Was it an honor to drink poison and accompany the king into the afterlife? Would this have been a way of allowing the royal court to continue on into eternity? Were those sacrificed chosen by lot, chosen for having granted particularly good service while living, or was this a punishment of sorts? Most likely, the deaths of these individuals spoke more to a lack of concern about their lives than anything else. The lives of these people were understood to be less valuable than the lives of the royal family. Thus, they could be sacrificed so that the royalty could have some material benefit in the afterlife and as a ritual demonstration of royal authority to those still living. This was a highly stratified society where not all lives were equal.

The development of highly stratified social relationships is one of the major hallmarks of this period. The Royal Cemetery of Ur, the Great Pyramids of Giza, the Valleys of the Kings and Queens, the royal tombs near Anyang, the warrior barrows of Europe, and the kurgans of central Asia are all funerary monuments in which the prominent social role of the dead was publicly demonstrated. The ability to force people to invest resources into some mortuary complexes and not others signifies a vast gulf between the rich and the poor, elite and non-elite. It reflects the different amounts of power that individuals within a society could hold. Grave goods, such as jewelry (think especially of King Tutankhamun's tomb), reflect the fact that people had different access to material wealth. Some people could own gold and fine exotic wares; some people were themselves the property of others (slaves or members of an ancient absolutist political entity).

Archaeologists find that social relationships were often mediated through objects. Large houses set the wealthy apart from the poor, the latter dwelling in small or less well-made homes. Expensive objects such as jewelry, fine art, fashions, or rare foods are also markers of wealth and status. It is on these types of evidence—material manifestations of

No one knows how the individuals who were killed to accompany the kings and queens of Ur must have felt about their sacrifice. Was it an honor to be killed and accompany the king into the afterlife?

difference—that archaeologists reconstruct ancient social relationships. For an archaeologist, it is not the monetary value of the objects that he or she discovers that is exciting; rather, it is what those objects can tell him or her about an ancient society.

Divisions of wealth and status are one marker of a larger series of social processes that were transforming the world during this period. People had begun to live in closer proximity to one another and had developed transportation technologies that effectively decreased the distances between one another. As greater numbers of people began interacting with one another on a very regular basis, new types of institutions developed in order to mediate these relationships. Political organizations and religious institutions were among the most prominent of these institutions. The development of these institutions is one of the most noteworthy accomplishments of civilizations in this period, an accomplishment that provided the basis for many of the institutions that still mediate social relationships today.

The basis for the development of many of these social mediators was writing. The first written languages appeared during this period, and this technological innovation allowed humans to communicate with one another through space and time. Communication no longer had to be between individuals in close proximity to one another. A scribe in Egypt could write on a tablet that could be sent to Cyprus and read by a scribe there. A Mesopotamian scholar could read the scientific findings of a scholar who had recorded his observations centuries ago.

A social institution that seems to develop quite naturally out of writing is codified law. The period from 4000 to 1000 BCE features the earliest examples of laws that are written down. The most noteworthy is the so-called Code of Hammurabi, but it is not the oldest. While modern scholars are uncertain about the precise role that these ancient legal precepts played in early society, from the volumes of legal cases and contracts that have been recovered, scholars can be certain about the prominence that legal precepts had in mediating ancient social relationships. These laws governed life at many levels, including relationships within a family (or in the creation of a new family through marriage), the treatment of people of different statuses, and interactions with foreigners. Shared legal precepts united many regions of the world in this period while simultaneously rigidly fixing the differences between peoples.

■ Introduction: The Family

Discerning family structure and organization from archaeological remains can be relatively difficult. One of the methods through which archaeologists approach this

topic is to study the remains of households and the spatial relationship of artifacts within the building. Thus, for archaeologists, the “household” is often what is explicitly studied, as op-

posed to the “family” per se, since the physical structures of houses often survive at archaeological sites. However, numerous conclusions about families can be drawn from the analysis of the household. For example, a typical rule of thumb is that each member of a household needs approximately 108 square feet (10 square meters) of space. This does not account for differences in status among members of the family (likely children needed or were granted less space than adults) and different uses of household space (storage space and cooking space are not usually counted as “living space”). In very rough terms, though, archaeologists can extrapolate how many people lived in the household.

Based on analysis of household size, extended families were likely more common in the period from 4000 to 1000 BCE than were nuclear families. A nuclear family is one married couple (or group, if the society is polygamous) and their offspring. An extended family consists of more than one marital group or numerous generations all living within the same structure. In polygamous societies, more than one wife (or much less frequently more than one husband) lived within the same household. Usually, if more than one wife was present, these wives were ranked in status. For example, in Near Eastern society, if a wife was unable to bear children, a husband was sometimes able to take on a secondary wife for the purpose of having children, although his first wife retained authority as the “first wife.” In societies where slavery was present, slaves would often live in the households and may have been treated, in some cases, as family members.

For extended families in this period (at least those for which we have written evidence), the oldest male of the household was understood to be the head of the family. From at least the era of the Shang dynasty in China (and likely earlier), the ideal of Chinese family life was for the oldest living male in the household to wield almost legal authority over other members of the household. Families in Syria-Palestine seem to have been structured along similar lines, with the oldest living male heading the household. Similar situations were likely present in ancient Greece of this period, Egypt, Mesopotamia, and perhaps elsewhere. In many parts of the ancient world, this type of family structure was understood to

be the basis of political organization, a type of organization called “patrimonial.” In patrimonial systems, the leader of the society (often a king) was thought to be the “head of the household,” and the entire society was seen as one extended household. Thus, all members of that particular kingdom were thought to be members of the king’s extended family, and family names (such as father, son, and brother) were used to refer to different members of the governing group even if there was no biological relationship.

In many of the families of the period 4000–1000 BCE, dead ancestors were considered to be active members of the family group. In China, for example, ancestor veneration was very important, and deceased family members were given offerings or prayers and were consulted about family matters. In northern Syria during parts of the Bronze Age, deceased family members were interred in tombs beneath the house and thus remained physically present in family life.

—Kevin M. McGeough

Marriage and Divorce in Egypt

Marriage in ancient Egypt is a difficult subject to approach, as the Egyptians had no concept directly comparable to the contemporary western institution of marriage. The Egyptians did, in fact, have words that can be translated as “husband” and “wife” and even “widow” or “divorced person.” The typical Egyptian household revolved around the nuclear family, which was headed by a couple who had entered into the arrangement in some official capacity. There were loose conventions governing both the creation and dissolution of these couplings, although these arrangements were made on the individual or local level rather than on the state level. However, there was no religious or legal institution that can be neatly defined as marriage at any point in pharaonic Egyptian history. In fact, in legal terms, marriage was essentially little more than an economic contract between individuals.

Most historical information about marriage derives from the New Kingdom and Late Period, thanks to the preservation of large numbers of legal and economic documents and personal letters from a handful of sites such as Deir el Medina. A more idealized picture of marriage

➤ DIVORCED WOMEN AND PROPERTY OWNERSHIP

Women could inherit, own, trade, and dispose of property as they wished throughout most of ancient Egyptian history. Upon entering a marriage, women retained sole rights to the property that they brought into the partnership. Married women could and did carry out business transactions and wrote wills independently of their husbands. One well-known example is the “Will of Naunakhte,” a document dating to the Twentieth Dynasty during the reign of Ramses V (ca. 1147–1143) drawn up at the request of a married woman who had decided to disown several of her children and divert their inheritance to other family members.

By the Late Period (beginning around the seventh century BCE), economic contracts drawn up between couples typically guaranteed that the woman would retain whatever property she held upon entering the marriage in the case of a divorce. Additionally, she would retain the original bride price paid by the man to her father at the time of marriage as well as an additional sum that her husband had agreed to pay her in case he decided to initiate a divorce. However, some of these contracts stipulated that the woman would forfeit this right if the divorce was the result of her adultery. Similar customs may already have been in place earlier, although they were not as formalized as in the Late Period.

—Megaera Lorenz

emerges from artistic sources (such as funerary depictions of married couples), wisdom texts, and literary texts.

The primary goal of an adult at any period of ancient Egyptian history was to establish a household (*gereg per*, the phrase most commonly translated as “to marry”) and have children. The importance of offspring was paramount. Not only did offspring have the responsibility of supporting their parents in life, but they were also expected to carry on their deceased parents’ mortuary cult, thereby ensuring their immortality. Thus, being married and owning a home were considered the ideal situation, and the ultimate goal of marriage was to produce offspring. Theoretically, an Egyptian individual could marry any person of his or her choosing. Egyptian men

and women both frequently married non-Egyptians. One famous literary example occurred in the Middle Kingdom story of Sinuhe in which the title character married the daughter of a Canaanite chief. There were also no strict limitations in terms of rank, although typically people chose spouses of similar social and economic status. Parents and family were probably very influential in the selection of potential spouses for their children. Some literary texts, such as the many love poems from Deir el-Medina, hint that mothers held a great deal of authority in their daughters’ choice of mates. Men often donated a bride price to the parents of their new wives.

There is no known formal ceremony associated with marriage in ancient Egypt. The couple would draw up a contract before witnesses stating the amount of property brought into the marriage by each party and how that property would be dealt with in the case of a divorce or the death of one of the spouses. Before the Late Period, these contracts fell under the broader category of the transfer deed (*imyt per*) and were not limited to specific use as a marital contract (i.e., this type of document could be used for any contract dealing with the disposal of property). It was only in the Late Period (Twenty-sixth Dynasty and later) that a formal system was developed specifically for drawing up marriage contracts.

In spite of the strong religious traditions associated with brother-sister marriage (the best example being the marriage of Isis and Osiris), such couplings were, in reality, extremely rare among nonroyal individuals before the Roman period. In the New Kingdom, spouses would often affectionately refer to one another as “brother” and “sister.” This practice occasionally confuses attempts to sort out actual kin relationships in texts from the period, but numerous genealogical analyses have effectively demonstrated that the usage of these terms between married individuals was figurative in most cases.

Polygamy was also uncommon among nonroyal individuals, and polyandry (the marriage of one woman to more than one man) is completely unattested at this point. There are a few cases of references to multiple spouses (i.e., a second or third wife), but these may refer to subsequent marriages rather than polygamous situations. Re-

marriage after divorce or the death of a spouse was an accepted and perhaps even encouraged practice for both men and women.

There are several terms in the Egyptian language meaning “wife” but relatively few meaning “husband.” This is largely because women were more often discussed than men in purely relational terms vis-à-vis their spouses. The one nonrelational title most often used to refer to married women was *nebet per*, or “mistress/owner of a house.” This term seems to reflect the role of a married Egyptian woman quite realistically. The *nebet per* carried out an administrative role within the household itself, managing household staff and domestic duties such as cooking and weaving. One wisdom text of the late New Kingdom, the Instruction of Any, famously advises the married man to mind his own business in the home and allow his wife to run the household unimpeded.

Textual sources indicate that divorce was fairly common and could happen for any number of reasons. Perhaps the most common was adultery, which was frowned upon largely for pragmatic reasons (e.g., any child sired through an extramarital affair would play havoc with the inheritance rules set out in the original contract). Divorce could be initiated by either the man or the woman, and no particular grounds were necessary. The greatest concern in the case of a divorce was the disposition of property.

Marriage and Divorce in the Ancient Near East

The institutions of marriage and the family were quite similar throughout the ancient Near East in the third and second millennia BCE. Lacking the religious and civil authorities' involvement,

➤ NUZI MARRIAGE CONTRACTS

In this case, the bride's brother and the groom's father agreed to this marriage contract. The bride-price has been established but not yet paid, and stipulations for a second wife for the groom are established. Besides corporal punishment, the groom loses his children and thus access to their inheritance if he violates the agreement with regards to a second wife.

“Tablet of contract of Puhi son of Shupantil with Uthaptae son of Zike.

They made a contract between them. Puhi has given his sister Nawaya to Hupita son of Uthaptae for marriage. Uthaptae will pay Puhi 45 shekels of silver.

If Nawaya does not give birth, Hupita may marry a second wife. If she does give birth, Hupita may not marry a second wife. If Nawaya gives birth, and Hupita takes a wife, Puhi shall strike him down. He shall take Nawaya along with her children. If Uthaptae treats Nawaya like his secondary bride, Puhi shall take Nawaya (back).

Whoever defies (the agreement) shall pay, in full, 1 mina of silver and 1 mina of gold.”

the marriage process focused on establishing the succession of inheritance for the two families. This focus increased the dependence upon contracts, oral or written, for the typically three-stage marriage process. These three stages involved the initial contractual agreement, which resembled modern-day prenuptials; the betrothal and payment of the bride-price; and the completion of the process, when the bride finally became legally subordinate to her husband rather than her father. Due to the contractual nature of marriage and the inheritance issues, several laws are devoted to marriage, divorce, and remarriage in the ancient Near Eastern law collections.

The initial agreement between families could occur years before the actual marriage. In the agreement, the groom or his parents and the bride's parents determined the bride-price that the groom would pay to his father-in-law. The inheritances of any eventual grandchildren were also determined, and penalties for divorce were set. Should the bride die before the wedding, her parents could substitute another daughter, demonstrating the importance of the family over the individual in the marriage process. Once the bride-price was paid, formal divorce proceedings were necessary. Lacking justification, the reneging party was heavily penalized. Furthermore, once betrothed, the bride-to-be was liable for adultery. Given this situation, the completion of the process was simply accomplished through oral declarations (for example, "you are my husband"), consummation, or cohabitation. The bride did not always leave her parents' household, and some agreements doubled as adoption contracts whereby the in-laws adopted the groom prior to the marriage and he left his own household. Notably, while slaves could marry other slaves as well as free persons, if a master married his own slave, she was emancipated with the completion of the marriage.

Throughout the ancient Near East, a qualified monogamy was the norm. While the husband held exclusive sexual rights to his wife, he was permitted extramarital relationships with nonmarried, including nonbetrothed, women. Possible sexual partners included his slaves, concubines, prostitutes, and widows. A wife's extramarital affairs, however, could be punished by divorce or by corporal or capital punishment for her and her paramour. With the exception of the king, polygamy was largely limited to the Old Assyrian and Old Babylonian periods and even then was confined to bigamy. Two notable exceptions to this rule existed: one when the woman was proven barren and the other in cases of levirate marriage. If a woman was thought to be barren, her husband was permitted to take a secondary wife. Several marriage documents from Nuzi, Emar, Alalakh, and the biblical story of Sarah and Hagar (Genesis 16) attest to this practice in the mid-second millennium. Levirate marriage, attested in Middle Assyrian, Hittite, and biblical law collections, occurred when the

widow of a childless husband married one of her in-laws and raised the resulting child as the child of the deceased.

Typically, either husband or wife could initiate a divorce. Grounds for divorce are not always provided in the documents and may not have been necessary. If the husband expelled his wife for adultery, slander, or financial malfeasance, he kept her dowry. Otherwise, she retained it. Remarriage was permitted after divorce, widowhood, or the husband's absenteeism whether due to military or unexplained circumstances. In such cases, a marriage contract was not necessary.

Childbirth in the Near East

Childbirth practices were relatively similar throughout the ancient Near East from Egypt to Syria-Palestine to Mesopotamia. Most of the evidence for these practices is indirect. Historians have used descriptions from mythological texts, artistic depictions, and information included in magical instructions to reconstruct what happened when a woman went into labor. The Egyptians especially disliked commemorating events that were dangerous or stressful, believing that writing something down could bring it into existence. The overall result for the entire Near East is that only limited information has been preserved about this important subject.

Conception was well understood to be the result of a sexual union between a man and a woman. However, the biological processes behind conception were unclear. In Egypt it was believed that the man placed the child directly into the belly of the woman. In Mesopotamia, conception was understood in almost botanical terms; the man planted the semen (in Akkadian one word served for both semen and seed) into the woman's belly, and conception was understood as similar to aspects of farming.

Numerous techniques were used to ensure that conception occurred. Magical incantations could be said, offerings could be made to the gods, various oils and ointments could be rubbed into the body, or any combination of these could be employed. Similar techniques could be used in order to prevent conception. The Egyptians also employed various techniques to ascertain whether or not a woman had become pregnant. One of these pregnancy tests had the woman urinate on a barley or emmer wheat seed. If the seed germinated, then it was determined that the woman was in fact pregnant. It has been subsequently shown that this test is relatively dependable. In Mesopotamia, it was thought that the gender or health of the baby could be determined by observing the changes in physical appearance that the mother's body underwent, especially skin blemishes.

When an expectant Egyptian mother went into labor, she was moved into a special room of the house or into a confinement pavilion. Delivery took place in special ritualized surroundings, set off from everyday activities. It is unclear if this was also the case in ancient Mesopotamia, although it seems likely. The expectant mother did not lie down to give birth. Rather, she squatted on stones or sat in a chair that had a portion of the seat removed; perhaps midwives or female relatives provided support on either arm. While this may seem uncomfortable, it is in fact much easier for the birthing woman, who can use gravity to help deliver the baby. After delivery, the mother was confined to the pavilion for a brief period. The child was granted a name in a naming ceremony, and special rituals were enacted with the placenta and umbilical cord.

Childbirth was a time of great danger for both the mother and the baby. Various rituals and mag-

➤ THE ABYDOS BIRTH BRICK

In 2001, the Pennsylvania-Yale Excavation to Abydos in Egypt, led by Josef Wegner, made an extraordinary archaeological find. Excavators working within a princess's quarters in the Middle Kingdom mayor's office discovered an ancient birth brick. Made out of mud like any of the thousands of bricks that the mayor's residence is composed of, this birth brick is unique in that it was plastered over and painted with magical symbols. On one face are depictions of the goddess Hathor as well as a woman holding a baby in a birthing arbor. Along the sides are images of sword-bearing animals cutting off the heads of other animals, likely symbolizing some sort of protective power. This is the only extant example of a birth brick, on which the mother would have knelt during delivery or on top of which the baby would have been placed immediately following delivery.

—Kevin M. McGeough

ical spells were enacted to protect mother and child before, during, and immediately after delivery. Special amulets were designed to provide protection against the dangerous spirits that may wish to harm the mother or child. Especially worrisome were the child-snatching demons, known as *lamashtu* in Mesopotamia.

Children in Egypt

The ancient Egyptians clearly differentiated childhood from adulthood, although it is less clear whether there were any further subdivisions in the Egyptian conception of childhood such as moderns hold (e.g., toddler or teenager). Scholars

THE EGYPTIAN WET NURSE

A wet nurse would have been a familiar figure to ancient Egyptian children from wealthy families. For Egyptian families that were able to hire a wet nurse, this woman would become a close member of the family, with the milk provided by the nurse establishing a symbolic link between the families akin to a blood tie. For the wet nurse, this position could be very beneficial. Payment could be quite good. In one particular instance the wet nurse was compensated by a family better than was a physician. The husband or biological offspring of a wet nurse could also benefit from the favors granted because of her employment by a high-ranking family. Indeed, acting as a wet nurse for a well-connected family could result in greater social mobility for the wet nurse's family. The occupation of wet nurse seems to have been a respected position in ancient Egypt. A frequent technique for showing divine favor in Egyptian art was to portray the goddess as suckling an individual, implying that the deity had the same close relationship to the individual as a wet nurse would have.

—Kevin M. McGeough

are unsure if any ceremonies formally marked the transition from childhood to adulthood. There are some indications that circumcision may have marked the male transformation from child to adult status, but this does not seem to have been the case for all periods of Egyptian history. Another possible initiation rite may have included wrapping a band around the boy's head. Female children may have been considered adults upon marriage, but this is not certain. Whatever the case may be, it is not clear exactly when an Egyptian child became an adult.

The differentiation between child and adult is most apparent in terms of dress and hairstyle, evidence that is well preserved in reliefs found on the walls of ancient tombs and from depictions in ancient statuary. However, when working with this evidence it is unclear whether these images reflect the real-life situation or are simply artistic conventions. In art, both male and female children are frequently depicted in the nude, although this fluctuates throughout Egyptian history. Given the preponderance of images,

Wall painting depicting an adult and children, Tomb of Inherkha, Deir el-Medina, Egypt, Eighteenth–Twentieth Dynasty. (Bojan Breceelj/Corbis)

it is safe to conclude that nudity was acceptable for prepubescent children. However, some children's clothes have been recovered archaeologically, including a linen dress from Thebes and a linen sleeve from Gurob, so it should not be assumed that nudity was the normative dress (or lack thereof) for children.

Childhood was not only marked by specific clothes (or more correctly the absence of such) but by hairstyle. Once again, style does not reflect gender differentiation. The most common style was to wear the hair in a sidelock, braided and curled on the right side of the head. The rest of the hair was either cut short or shaved off completely. Some variations are evident. Occasionally children are depicted with braids, with jewelry woven into the lock, or with short hair

but no lock. Hand gestures are similarly used as conventions in Egyptian art. Boys are typically seen sucking their middle fingers.

There is less evidence for the daily life of a child in ancient Egypt. What may be toys have been recovered archaeologically, including balls and animal figurines. Egyptian art and literature also hint at certain games that were played, especially acrobatic pursuits and role-playing games. Pets are often depicted along with children in tomb art. It is unclear whether this meant that children did normally have pets or if these were idealized images of childhood intended to perpetuate pleasant surroundings in the afterlife. Some children would have attended school, but we have little evidence for what that would have entailed or who would have had access to it. Most nonelite children would have to have engaged in some sort of work. For some children this would have meant following their parents around, working around the home or assisting in professional labor. In other instances, children may have had formal occupations working as servants, entertainers, or attendants for the elite.

It is assumed that infant mortality was very high in ancient Egypt. A cemetery associated with the New Kingdom site of Deir el-Medina contains the remains of many dead children in a variety of containers. At some sites the remains of infants were interred under the floors of houses or within household furnishings. Family size in ancient Egypt varied depending on various circumstances. Perhaps the most extreme was Pharaoh Ramses II, who had more than 150 children. More typical families would have between 2 and 6 children, perhaps more in the rare cases in which all children managed to live past infancy. Demographic evidence for Egypt is extremely limited since the Egyptians did not keep accurate birth and death records. Generalizations can be made based on the biographical information contained in private tombs.

Children in Canaan

Due to the paucity of Canaanite sources on the topic of children, we are left primarily with the Hebrew Bible and several texts from Ugarit (though technically just north of Canaan) as our main sources of information regarding children. Despite the fact that this population demographic was virtually powerless—ancient Israelite society being one that more clearly valued adults and elders (Prov. 3:2, 16:31), with parents having near absolute authority over children (Exod. 21:17; Prov. 23:13)—a number of references in the biblical and Ugaritic texts provide insight into the lives of children in Canaan in antiquity.

The birth of a child was seen as a blessing from God, especially in that children, once grown, provided labor for the family and an heir for the parents. That children were considered a blessing can be seen in both prayers of petition for children (1 Sam. 2) and in the joyful celebration for the arrival of a child (Gen. 21:6; Ruth 4:13–15). Such prayers of petition, though, were not limited to the would-be mother. Men also joined in petitioning God (or the gods) for an heir (Gen. 15:1–3; Aqhat in the Ugaritic narrative of Aqhat). The frequency of prayers for children in the Bible underscores the seriousness of the issue of childlessness. To be a married woman without a child was a rather unfortunate circumstance (Gen. 16; Jer. 18:21). It appears, though, that once a family was blessed with a child, the mother frequently contributed to the naming of the child (Gen. 29–30). Children were often named after local species of flora or fauna or after their ancestors, for instance, a grandfather. Alternatively, names might include a theophoric element; that is, the name of the god worshipped by the parents could appear in the child's name (e.g., Joshua, meaning "Yahweh saves"). Estimates suggest that an Israelite woman would give birth to an average of four children. With high infant mortality rates, however, only two would be expected to reach adulthood. Consequently, the average nuclear family would comprise approximately four members.

Children primarily received their education from their parents. Children were instructed in religious matters (Exod. 13:3–16; Deut. 6:7), vocations (1 Sam. 3), and the military (Gen. 14:14; 1 Chron. 12:8). Children were also taught to “honor thy father and mother” (Exod. 20:12). “Honor,” however, did not merely entail respecting the word of one’s parents but instead included honoring one’s parents after the parents had died. Children would be expected to oversee the burial and mourning rituals for their parents and the ongoing maintenance of the tomb. Further duties are listed in the Ugaritic narrative of Aqhat detailing the requirements of a good son. The good son contributes to the family in ritual matters and mundane matters. Ritual actions include setting up a stele (standing stone) in remembrance of one’s ancestors, offering incense and songs to the gods, and participating in ritual feasts. Mundane actions include defending one’s father in social circles and household chores such as patching the roof and cleaning clothes. Of course, children were expected to contribute to the well-being of the family, with boys assisting with farming or the family’s animals and girls assisting their mothers. As was just seen in the description of filial duties, though, we should not be too quick to assume a traditional division of labor, since the good son cleans his father’s clothes.

Should a child reach adulthood, issues of inheritance and primogeniture came into play. Typically, only sons would receive an inheritance of land upon the death of a father. If there was more than one son, the eldest would receive a double portion (Deut. 21:17). This privileging of the eldest son in a family is known as primogeniture. Besides receiving a double portion of the inheritance, the eldest typically received a special blessing (Gen. 48) and would succeed his father as head of the household. Exceptions, of course, exist. Jacob, by means of trickery, obtained the special blessing of his father, Isaac (Gen. 27), and Joseph, though the 11th of 12 sons, was deemed the favorite, receiving a special coat from his father, Jacob (Gen. 37:1–4). On the chance that a father would die without sons, daughters would be eligible to receive an inheritance, though this was considered exceptional (Num. 27:1–11).

Children in Mesopotamia

Children, particularly sons, were earnestly desired by the Mesopotamians, for who else would care for a couple in their old age and make offerings to ensure the well-being of their spirits after their death? Where children were more abundant than resources, the baby might be adopted by a childless couple. The Mesopotamian infant was protected in the womb against the baleful she-demon Lamashtu by magical amulets and incantations (in which the child was visualized as a ship on a dark sea carrying an unknown cargo). Abortion was illegal, although a recipe for an abortion-inducing potion shows that it was illicitly practiced.

Babies were fed by their mother or by a paid wet nurse for their first two or three years. During this time they were still threatened by Lamashtu, who was held responsible for infant mortality. The average family was lucky if more than two or three of their children survived into adulthood. Thereafter life expectancy was good, 70 being considered a good age and 120 stated as the greatest age that the gods would allow; timely death was not feared but welcomed. Fifty was considered too young to die; early death through disease, accidents, or warfare was regarded as a sign that the gods, particularly the family deity, had turned their back on the individual concerned, often because of some consciously or unconsciously impious act.

Soon after birth the baby was given a name, often incorporating the name of the family god or the family’s city of residence. At first it slept in a basket, hushed to sleep by a lullaby sung by its mother, lest its crying disturb and anger the gods. During the day she carried it around in a sling.

Once out of infancy children were expected to help their parents and learn the skills they would need in adult life, usually following their parents' occupation. Often children worked alongside their parents, in the fields or at their work. For example, the huge textile factory in Ur-III-period Guabba employed 1,800 children as well as more than 4,000 women. The children of the well-to-do attended school. In one Sumerian text, a father berates his son for idling instead of attending school, saying that he has been spared the chores and labors that most children had to undertake in support of their families.

Life was not all work. Little model animals set on boards must have been pull-along toys for small children, and their older brothers and sisters played knucklebones, dice, and board games or skipped and danced to the music of a flute. Board games had a more serious side too, being used in divination. Boys might accompany their fathers for hunting or practice shooting at a target. Literary skills could be honed in debating contests. On occasion there would be profes-

sional entertainers to watch: jugglers, wrestlers, clowns, acrobats, instrumental musicians, singers, snake charmers, and performing bears.

■ Introduction: Social Classes

In the period from 4000 to 1000 BCE, social differentiation at its most extreme emerged. At various times in Egypt, Mesopotamia, and China human sacrifice was present, which at heart reflects conceptions that some humans are more worthy than others. In these cases of human sacrifice, a wealthy or powerful individual wanted servants to accompany him into the afterlife.

Human sacrifice may be the extreme example of this high level of social differentiation that appears in this period, but it is not the only example. Many of the era's greatest monuments and achievements came at the expense of people exploited by more powerful individuals. The Pyramids at Giza, while not built by slaves (a common misconception), were built by laborers working for the state, using state resources acquired through taxation. The pyramids, as tombs for kings, reflect social stratification in that they were a visible marker of the extreme

importance of one individual over another. Throughout Europe, the Middle East, and China, wealth in this period becomes very unevenly distributed; archaeologists are easily able to differentiate the houses of the poor from the houses of the wealthy in these areas.

The first evidence for slavery comes from this period as well. While this institution may have existed even earlier, it is very difficult to identify slaves in the archaeological record; textual accounts, usually laws about the treatment of slaves, provide the firmest evidence for slavery. In this period, slaves were either foreigners captured in war or people who had become so impoverished that they were compelled to sell themselves into slavery in order to survive. The ability for one person to own another is one of the unfortunate contributions that humans in this period made to world history.

—Kevin M. McGeough

► THE LANGUAGE OF SOCIAL DIFFERENTIATION

When ancient historians talk about inequality, they use very specific language to refer to very specific concepts. Rank is the relative position that an individual has in a society and can be determined by any number of means. Status likewise is the relative position that an individual has in a society, but it is determined by individual achievements and displays of that achievement. Class is the relative position of a group within a society and defined by economic relationships.

—Kevin M. McGeough

Hammurabi's Law Code and the Tripartite Structure of Mesopotamian Civilization

The most fundamental document from the Old Babylonian period (2000–1500 BCE), the Code of Hammurabi is one of the earliest law collections from Mesopotamia, serving as a vista into

► LEX TALIONIS

The following law sections, making up part of what is known as the *lex talionis* or “law of retribution” (the law is also found in the Hebrew Bible, Exod. 21:22–27), reveal strikingly the division of social classes invoked in judicial settings of the Old Babylonian period. The translation is Roth’s 1997, with a few minor alterations:

“Section 196: If an *awīlu* should blind the eye of another *awīlu*, they shall blind his eye.

Section 197: If he should break the bone of another *awīlu*, they shall break his bone.

Section 198: If he should blind the eye of a *muškēnu*, he shall weigh and deliver 60 shekels of silver.

Section 199: If he should blind the eye of a *wardu* owned by an *awīlu* or break the bone of the same, he shall weigh and deliver one-half of his value (in silver, i.e., ≈ 10 shekels).”

—Ben Thomas

M. T. Roth, *Law Collections from Mesopotamia and Asia Minor*, Society of Biblical Literature Writings from the Ancient Near East 6, 2nd ed. (Atlanta: Scholars Press, 1997), 121.

all aspects of ancient Babylonian life. It was compiled under the auspices of King Hammurabi of Babylon (ca. 1792–1750 BCE) toward the end of his reign. While most agree that it is not a true code in the sense of Justinian’s *Institutions* or Napoleon’s *Code Civil*, much of its subject matter is disputed, not least of which is the discussion of the three primary social strata: the *awilum*, the *mushkenum*, and the *wardum*. Defining the *awilum* and *mushkenum* is slippery, since they are only legally distinct in the Old Babylonian period. The *awilum*, often simply translated as “man,” may simply refer to an ordinary individual in any given section of the code. However, when used in conjunction with the *mushkenum* or *wardum*, he always represents a freeman (i.e., free from debt). The *awilum* usually owned land and performed the role of household head.

The *mushkenum*, a West Semitic term meaning “subordinate,” after the Old Babylonian period became a designation for someone stricken by poverty. It has even come into the Romantic languages with the same connotation (Italian *meschino*, French *mesquin*). Yet in the code its usage is too specialized to be merely construed with “the poor.” In relation to the *awilum*, the *mushkenum*’s social standing was inferior. It may be, however, that the *mushkenum* belonged to the king, and as such legal requirements may have been required since the *mushkenum* were not defended by customary law. Rights explicitly guarding this group are often put adjacently to those of the palace (Section 16). Due to the dubiety of defining the roles of the *mushkenum* and the *awilum*, many refrain from translation and leave them simply in transcribed Akkadian.

Slaves (*wardum* class) were both of indigenous and foreign nationality, sometimes prisoners of war. Overall, slaves were relatively few in number, as compared to the Greco-Roman times, since agriculture and herding were not based on slave labor. Some slaves were forced to sell their wives, children, and even themselves into slavery due to economic hardship. Slavery was not a fixed social condition. Slaves could purchase their freedom and even buy land. The average price for a slave was 20 shekels of silver but was sometimes as much as 90 shekels. The normal wage paid to hired laborers was 10 shekels annually. It was the wealthy who were really only able to afford slaves. Thus, one can understand

why runaway slaves are often a topic of concern for the code and were given a distinct lock of hair to make public their status.

Fees and punishments varied according to the social condition. This is clearest in the famous *lex talionis*, or “law of retributive justice.” An awilum would have to pay more for damages inflicted upon an awilum of equal or superior rank than to a mushkenum. However, social barriers could also work in favor of the lower classes. The mushkenum had to pay 10 shekels of silver for striking the cheek of another mushkenum (§204), yet an awilum would have to pay 60 shekels for the same offense to an awilum. It stands to reason that an awilum should pay in accordance to his pecuniary means, which was of course more substantial than for the mushkenum.

Warrior Classes in Bronze Age Europe

The emergence of Bronze Age warrior classes reflects important social, economic, and technological developments in European prehistory. Iconographic and burial evidence associate warriors with weapons, armor, and related material culture that embodied prestige and power. Only select individuals were associated with warrior artifacts, indicating the restricted nature of their social and perhaps political or economic status within communities. Although the roles of warriors likely varied between regions and did not always involve warfare, warriors are consistently portrayed throughout Europe, attesting to widespread cultural influences during the Bronze Age.

Social stratification and the emergence of Bronze Age warriors are related to agricultural developments and the growth of bronze metallurgy. Although settlements were small and dispersed during the Early Bronze Age, local agricultural production intensified with sedentism

and the introduction of the ox and plough. Food surpluses allowed segments of local populations to engage in nonagricultural activities, which included metalworking. Metallurgy existed before intensive agriculture, but the demand and widespread acquisition of metals and the understanding of their properties did not occur until the late third millennium BCE, in central Germany.

Bronze metallurgy led to the production of weapons and material culture of prestige, which became a protocurrency. Naturally occurring copper and tin were rare, requiring trade networks to transport metal ores from prominent sources in the Carpathian Basin and the Caucasus to meet demand elsewhere. Bronze metallurgy became widespread in central and northwestern Europe with the exploitation of copper sulphide ores from the Alps and German-Bohemian hinterland, as did lavish grave goods and the appearance of warrior burials. During the Bronze Age, communal (multiple-person) burials, which were popular during the Neolithic period and the Copper Age, were abandoned in favor of individual burials, which marked an ideological shift in the perception of identity and the recognition of social stratification. By the Early Bronze Age, most humans were interred in single flat burials, some accompanied by weaponry and presumed to be warriors; elaborate burials included bronze weaponry, wagons, and ceramic vessels associated with feasting.

With long-range trade and metallurgy came changes in warfare. In the Early Bronze Age, metal projectile points replaced stone arrowheads, and the bow and arrow became the chief mode of combat. With metallurgical developments in the Carpathian Basin, daggers became increasingly important, their blades later elongating into rapiers and swords, a particularly important phenomenon in tumulus burials along the Rhine and upper Danube. By the Late Bronze Age, thrusting spears were widespread, as were daggers and swords, indicating that close-range combat was common. Rock carvings and other iconographic evidence suggest that shields were common but made of organic materials such as wood and animal skins, which rarely preserve.

Although metallurgical developments were vital to the emergence and identity of warriors, their roles in warfare and trade are not obvious. Many weapons in warrior burials and ritual

► THE DEVELOPMENT OF SOCIAL STRATIFICATION AND THE EMERGENCE OF BRONZE AGE WARRIOR CLASSES

Did social stratification and the appearance of warriors occur out of societal necessity or individual interests? Functionalist understandings of social stratification contend that larger sedentary Bronze Age communities had different needs than Neolithic or Copper Age societies, including systematic labor organization, resource distribution, and security. These responsibilities required the leadership of select individuals, and warrior classes may have emerged in response to communal need. Nonfunctionalist perceptions of social stratification claim that certain individuals accumulated and protected material wealth gained through the control of interregional trade networks. These individuals were prominent socioeconomic elite who may have included warriors or employed them for security and protection. What do you think?

—Noah V. Honch

deposits would have been ineffective in battle. Many helmets could not have withstood impact blows, and others had protruding horns that would have been awkward in combat. Many breastplates were heavy and mechanically awkward, making fighting extremely difficult. In such cases, metal artifacts were probably of ritual or symbolic significance. As such, some so-called warrior burials did not contain warriors of battle but instead contained important individuals whose power and social stature were symbolized by warrior artifacts, which were connected to elaborate ceremonies and purposeful display.

Extensive use wear on the surfaces of weapons, however, attests to the reality of warfare. A number of buried individuals, having died in battle, have projectile points embedded in their spinal cord or pelvis. Hillforts and fortified settlements also appear with the expansion of weapons manufacture. Many fortifications exploited natural boundaries for defense and overlooked waterways and roads that were important to metallurgical trade routes and may have marked important geopolitical boundaries; these facilities were probably manned by warriors.

A dramatic transition in the representation of warrior classes occurred upon the collapse of the Mycenaean civilization during the Late Bronze Age. Population movements along the Middle and Lower Danube ushered in the Urnfield period during which the dead were cremated, placed in funeral urns, and buried in cemeteries. Urnfield burials overturned traditional inhumation practices in central Europe and peripheral areas of the continent, carrying new technologies (e.g., sheet bronze working) and further outlets of elaborate display and prestige. While the intellectual or theological belief systems behind emergent Urnfield burials are not clear, the memories and achievements of warriors remained important and continued to be symbolized by weapons, armor, and prestige objects.

Mesopotamian Slavery

Slaves—*wardum* in Hammurabi's law code—occupied the lowest rank in Mesopotamian society. Textual clues suggest that slavery already existed by the later fourth millennium BCE. Initially, all or most slaves were war captives and generally female. Male prisoners were often slaughtered, although they might be restrained in a neck stock until cowed enough to be used as slaves or blinded to make them easier to manage. Enslavement was not necessarily permanent, and some prisoners became *mushkenum*. By Old Babylonian times, prisoners of war of either sex were becoming economically more important and were therefore valuable booty. Several letters from Mari and Karana's royal la-

dies refer to promises of new slaves after a successful military campaign, and most or all of the slaves in the Mari palace workshops were prisoners of war. These captives were initially state property, sent to work in the temples or palaces, but in late Assyrian and Neo-Babylonian times, even private soldiers could acquire prisoners as their private booty, often selling them to wealthier individuals or hiring them out as prostitutes.

By the second millennium there was a flourishing trade in slaves, fed by slave-taking raids in addition to the flow from regular warfare. In Old Babylonian times, tribesmen and women from the eastern mountains were popular as slaves, but the mountains to the north and the desert to the west also supplied tribal captives. Slaves did not come cheap, from 20 to as much as 90 shekels of silver at Old Babylonian rates compared with around 10 shekels a year to hire a laborer, but in addition to work they could give a return on investment by producing children. Many of the slaves in Mesopotamian households and institutions were the offspring of slaves or of slave women and free men.

Not all slaves were war captives or their descendants. Enslavement was a punishment for certain crimes in Hammurabi's code. A substantial proportion of slaves in most periods were local people whom misfortune had forced into slavery. In times of extreme hardship, for example during a long siege, it was a recognized practice for a man to sell himself or members of his family to the temple or palace to keep them from starvation. In Neo-Babylonian times children could be dedicated to the temple as oblates for the same reason. They were free to practice a craft or other occupation but had to pay the temple part of their earnings.

Debt drove many into slavery. High rates of interest on loans (one-fifth) and on loaned grain and other perishable goods (one-third) meant that it was easy for individuals who suffered a succession of bad harvests or a run of ill luck to spiral into debt. A man could bind himself or a member of his family to serve his creditor for a period of time—fixed at three years in Hammurabi's law code—or sell them to pay off the debt. Unlike foreign captives who were generally slaves for life unless manumitted, debt slaves could

redeem themselves by paying off the debt. Periodically an enlightened ruler (such as Lipit-Ishtar of Isin or Ammisaduqa of Babylon) would annul such debts, releasing those trapped in debt slavery.

The Late Assyrian kings deported vast numbers of conquered people; unlike war captives, these initially retained their freedom, and many settled peacefully into their new homes, enjoying rights equal to those of the native population. But from the reign of Sennacherib onward, their status changed. They now became royal slaves and were distributed by the king alongside other booty, some becoming the property of temples, nobles, and private citizens and others being conscripted into the army or serving the palace by cultivating its fields and gardens or tending its flocks and herds.

Kings offered many of their prisoners of war to the temple, and it was not uncommon for private individuals to dedicate slaves as offerings. Slaves might also be transferred from private to state ownership to pay taxes. In the third millennium most temple workers were free employees. Temple and Crown estates were cultivated by free tenants, and public works were undertaken largely by citizens as *corvée* labor. Increasingly as time went on, however, slaves worked alongside, or instead of, free individuals on public works, in state factories, and on large royal, temple, or private estates.

Most domestic slaves undertook household activities, but if they had a particular skill they might work as craftsmen or craftswomen in the home or be hired out to make a profit for their owner. In later times, slaves could be apprenticed to learn a useful trade or skill, such as baking, cobbling, brewing, or weaving. In some cities or in some periods, slaves were allowed to operate in many ways like free individuals, earning an income by working; owning and renting out houses, land, animals, and even their own slaves; and becoming involved in business ventures. However, they had to make their owner a regular payment (*mandattu*), and they could not buy their freedom but could still be sold by their owner, their earning power and accumulated savings increasing the price they fetched. Temple slaves could attain senior administrative positions but likewise remained slaves.

Careful records were kept of the origins and personal details of state-owned slaves, who were housed in barracks. Slaves were rarely physically restrained but were identified by their hairdo or *abbuttum* (*apputtum*), probably a style of forehead hair since “clearing the forehead” was the term for manumission. It was a grave offense, attracting severe punishment, for a barber to shave this off or for anyone to coerce him into doing so or to aid a slave in escaping. On the other hand, at least at Mari, slaves themselves were not punished for attempting to escape, although habitual bolters might be chained. A more permanent mark, branded on the forehead or hand, was initially rare but had become usual by the first millennium BCE. One text recorded an escaped domestic slave’s attempt to turn her ownership mark into a temple brand to improve her lot. Temple slaves received the same rations as free employees: basic food, with extras on feast days, and an allowance of clothing or wool. The conditions of domestic slaves varied, but they enjoyed no legal protection against harsh treatment, and their families could be split up and sold separately.

On the other hand, slaves were often valued and well-treated members of the household and were usually few in number. Letters found at Mari and Karana show that it was thought bad

form to get rid of a long-serving slave; one records a combined protest by the other household slaves against such an action, and another was directed by a slave to King Zimri-Lim himself, begging him not to sell her mother. A slave girl who had borne a son to her master could not be sold, and she and her children became free on their master’s death, whereas other slaves were inherited by the next of kin. Other slaves might be granted their freedom on the death of their owner; the children of a freed slave automatically became free too.

■ Introduction: Ethnic Identities

Human groups had been differentiating themselves from other human groups long before 4000 BCE. Yet between 4000 BCE and 1000 BCE, there are hints that people had started to differentiate each other on the basis of what we today call race and ethnicity. Generally, the term “race” refers to classifications based on biological or physical difference. This conception, while still common in public discourse, is less favored in academic circles, since with the rise of genetics as a science, it has become clear that the traditional markers of racial difference are in genetic terms almost negligible. Ethnicity is different from race in that

these categories are based on similarities within a group (and differences to other groups) derived from cultural practices and historical circumstances. An ethnic group usually shares a language, cultural values, territory, and perhaps shared origins. For a group to be an ethnic group, the members must have a shared belief that they are members of a group.

Ancient conceptions of what constitutes ethnicity would not have lined up evenly with modern ones. In the languages of this period, there are no terms for the abstract concepts of ethnicity and race. Yet there were words to describe someone as a foreigner or stranger, and there

were artistic conventions for depicting this kind of difference. The traits that made someone “foreign” included speaking a different language, wearing different clothing styles, engaging in different cultural practices (e.g., circumcision), and being born in a different location. These differences, however, do not necessarily line up with specific political entities. For example, the Canaanites (who dwelt in what is now known as Israel) were seen as a distinct group of people (with a shared language, religion, fashion, and cultural practices) even though they were never a unified political body.

One must be very careful when studying ancient race and ethnicity to not impose modern baggage on the ancient world. Do not presume that modern ideas of race were held by the ancients. The Egyptians, for example, did differentiate themselves from people in the Levant, the Greek world, and the rest of Africa. Skin color, however, was not one of the typical means of this differentiation. In Egyptian art (as well as Minoan art), skin color reflects gender, not race. Dark-skinned individuals are males; white-skinned individuals are female.

—Kevin M. McGeough

Conceptions of Ethnicity in Ancient Egypt

The ancient Egyptian view of ethnicity is complex, demonstrating a mix of conceptions as well as changes over time and situation. It is unclear what ethnicity Egyptians themselves were, partially because, at least to begin with, the country consisted of a heterogeneous ethnic background. There have been various scholarly debates over the ethnic origins of Egyptians, employing everything from linguistic analysis to studies of artistic representations. While disagreements are likely to continue, it seems clear that as the country became unified it was made up of a range of groups, more heavily African in the south and Levantine in the north. The Egyptian language is characteristic of this. Often designated as Afro-Asiatic, it demonstrates consistent characteristics of both Semitic and African language families. While the Egyptians always maintained a sense of local identity (e.g., a Theban, an oasis man, etc.), they also developed a

strong sense of national identity, separating those who were Egyptians from those who were not. The distinctions were god-given. A hymn to Amun-Re states, “It is Atum who has created men; who has defined their nature and has made them live; who has distinguished them one from the other by the color of their skin.” Egypt was considered the center of creation, and thus Egyptians held a central place among ethnicities.

The Egyptian view of others was complex, receiving a mixed treatment in available sources. Two divergent outlooks are apparent, which Loprieno has classified as the *topos* and *mimesis* views. The *topos* view, promulgated in official texts and representations, held a hostile regard toward those of non-Egyptian ethnicity. Just as the ordered and organized world was surrounded by an ever-impinging chaos, so Egypt was surrounded by ever-impinging foreigners. Foreigners became the epitome of chaos, and the need to subjugate them was as long lived as the idea that order must conquer chaos. Thus, as all of chaos should become ordered, all of the world, *de facto*, belonged to Egypt and must be controlled by it.

Of the many texts promulgating the *topos* position, two examples will suffice. The prophecy of Neferti outlines that a period of chaos in Egypt was the direct result of the incursion of foreigners and that as a king arose who would set things right, “Asiatics will fall to his slaughter; Libyans will fall to his flame . . . Asiatics will not be allowed into Egypt,” and due to these actions, “Order will return to its seat; chaos is driven out.” In an Eighteenth Dynasty letter to the viceroy of Kush, he is warned to “not trust Nubians, beware their people and their magic.”

Yet in more mimetic sources, such as fictive tales, biographies, and mundane texts, a different view of foreigners appears. Here we find foreigners who have acculturated to Egypt, married Egyptian natives, hold Egyptian positions of trust, and raise Egyptian families. Even foreigners who came to Egypt as slaves, likely as part of the booty of war, could be raised to positions of trust. We know of Semitic and Nubian tutors, temple gatekeepers, generals, and viceroys. Some immigrants adopted Egyptian names and seem to have completely integrated into Egyptian society. There are even a few instances of people

with foreign names being referred to as Egyptians. Some foreign ruling groups were hated, and others were acculturated and well received. Some foreign enclaves in Egypt lived peacefully with their neighbors, while others were treated with hostility. But throughout Egyptian history, distinctions were made between ethnicities.

Akkadian Personal Names

Akkadian names were given at birth or soon after. This fact is demonstrated by names that reflect the circumstances of the birth itself, such as Ippushqim-usi ("He came out with difficulty") or Tulid-dannam ("She [the mother] has given birth to a strong one"). Some names seem to be short prayers for a successful birth, Suchur-Sin-lisi ("May he come out to the light of the moon-god Sin"). The name Ikshud-appashu ("His nose has arrived") is a particularly interesting example of a name that alludes to birth circumstances. According to J. J. Stamm, this name probably reflects the fact that the child was born as a breach. In a normal (head-first) birth, the child's nose "arrives" at the beginning and so would not, it seems, warrant any notice. Only in a breach birth, whose end is marked by the "arrival" of the nose, is there cause for notice. Since, in antiquity, live breach births were rare, this name expresses the namer's joy upon the successful completion of what must have been a difficult birth. The circumstances of birth are also reflected in a number of names that refer to the

child's birth date, such as the names Mar-um-eshra ("Son of the twentieth day of the month") or Nisanitum ("Born in the month of Nisan").

Very often, Akkadian personal names are theophoric, meaning that they refer to a particular god in some way. Some of the simplest theophoric names use a genitive construction to evoke the relationship between the child and his or her god. Names in this category include: Naram-Sin ("Beloved of the Other"). Theophoric names express the namer's wish for the child, such as Nabu-bullissu ("Oh god Nabu, make him healthy!") or Nabu-kudurri-usur ("Oh god Nabu, preserve my heir!"), which is the original Akkadian name of the famous Babylonian king Nebuchadnezzar. A related group of names are those that are, in strictly grammatical terms, the child's own prayer to the god, such as Nabu-ballitanni ("Oh god Nabu, make me healthy!") and Ashur-tursanni ("Oh god Ashur, protect me!"). Similarly, names such as Nabu-shuma-ushabshi ("The god Nabu has made a name"), Adad-ubla ("The god Adad has brought [this child] to me"), Ibni-Ea ("The god Ea has fashioned [this child]"), or Iddin-Ishtar ("Ishtar has given [this child]") express the namer's thanksgiving to the god for the child. Other theophoric names, such as Nabu-naid ("The god Nabu is praiseworthy") and Sin-shar-ili ("The god Sin is king of the gods"), are more abstract statements about the god. There are also names that refer to the human king, such as Marduk-sharra-usur ("Oh god Marduk, preserve the king!").

Speakers of Akkadian also gave names taken from nature. The names of animals, such as Shel-ebum ("Fox"), Burtum ("Cow"), or Habasiru ("Mouse"), and plants, such as Ishhunu ("Vineyard") or Lurindiya ("My pomegranate"), are all known as names of people.

There is evidence for the use of nicknames in Akkadian. Generally, as in English, these nicknames preserve the basic sound of the name but transform it in some way. Examples of nicknames include Gimillum for Gimil-Marduk ("Granted by the god Marduk"), Wardum for Warad-Ishtar ("Servant of the goddess Ishtar"), and Kabtiya for Kabti-ilani-Marduk ("The god Marduk is honored among the gods").

Ancient Ethnicity in South Asia

Ancient ethnicity is a complex and often controversial subject. Ethnicity is often defined on the basis of language, culture, and race, but these need not be congruent. For example, in modern South Asia there are many languages. Some are spoken by biologically distinct groups, in restricted geographical regions, or by certain tribal groups or members of particular religious communities. Most, however, are not. Through time, biological distinctions have been blurred by intermarriage, linguistic differences have been accentuated by interactions such as bilingualism, and cultures have constantly evolved. Identifying ancient communities who would have seen themselves as distinct ethnic groups is therefore fraught with difficulty.

Physical anthropology, literature, language, and archaeology are the principal sources of evidence for attempts at reconstructing ancient ethnicity. These also shed light on religion, culture, economy, human geography, and other aspects of life important in people's characterization of their own ethnicity.

Skeletal and genetic evidence indicate that most of South Asia's population is descended from people who settled here during the Pleistocene and that there has been almost no contribution to the gene pool by women from outside the subcontinent. However, genetic studies suggest that a small number of men from West Asia settled here at an early date. Skeletal evidence from northwestern South Asia indicates the arrival of small numbers of people from the west in the fifth millennium and from somewhere outside the subcontinent in the early second millennium BCE. The majority of South Asians be-

long to the Caucasoid general racial group, but many in the Himalayas and extreme eastern regions are Mongoloid, part of the same general group as East Asians; they presumably colonized these regions from the east.

The earliest South Asian literature is the Rig-Veda, hymns composed around 1500–1000 BCE. The chronology of their composition reveals a gradual eastward shift from west of the Punjab to the upper Ganges-Yamuna doab. The Rig-Veda describes a warlike society, with horses and chariots, that kept cattle, and, above all, practiced the rituals that defined them as Aryas. Unflattering descriptions may indicate that their non-Arya enemies were physically distinct and spoke an incomprehensible language. Nevertheless, the Aryas occasionally allied with them; the Aryas also fought among themselves.

The Rig-Veda reveals an anthropomorphic male-dominated pantheon, and its rituals include precisely organized sacrifices and the drinking of sacred *Soma*. Similar gods and practices are found in the contemporary Iranian sacred book, the Avesta, but they contrast with the tentative reconstructions of Harappan religious practices and beliefs, which probably included goddesses, animism, ritual bathing, and a fertility cult, features that appear among the rich range of Hindu practices and beliefs of post-Vedic times.

Most South Asians today speak Indo-European languages. Sanskrit, the language of the Rig-Veda, belongs to this language family, as does Old Iranian. These separated from their common ancestor, Proto-Indo-Iranian, probably in the early second millennium. Progressive changes in the language of the Rig-Veda indicate that through the later second millennium its speakers were in contact with speakers of languages that had features such as retroflexion, characteristic of the Dravidian and Austro-Asiatic languages but absent from other Indo-European languages, demonstrating that this contact took place in South Asia. Dravidian languages today are largely confined to southern India, but once they were spoken from Gujarat through western into southern India and possibly in Sindh. It is still unclear whether Dravidian originated in the subcontinent or outside. The few modern speakers of Austro-Asiatic in India are confined to

IDENTITY AND THE INDO-ARYANS

Ethnicity is often a major component of identity, allowing people to define themselves. Pakistanis can use their Muslim faith as well as their geographical home in defining national identity. The inhabitants of much of India speak Indo-Aryan languages and practice the Hindu religion, of which the most sacred texts are the Vedas. Both language and religion are therefore major elements of their national identity. Most Indians are happy to be the inheritors of a rich cultural tradition in which indigenous developments have been mixed with the contributions of small numbers of settlers from the many foreign incursions that have taken place in historical and earlier times. For a vociferous and at times fanatical minority, however, it is unacceptable that the weight of evidence indicates that both the Indo-Aryan language and the Vedic religion came from outside and that the Indus civilization was the achievement of non-Indo-Aryan speakers who did not practice Vedic religion. They therefore attempt, generally by strong words rather than reasoned argument, to identify the Indo-Aryans with the Harappans. This is to misunderstand the whole situation, creating rigid boxes in which separate ethnic identities each equate with a single language, genetic background, and culture. In truth, the inhabitants of India are biologically, culturally, linguistically, religiously, and in every other way the inheritors of both the Vedic Indo-Aryan and the Harappan traditions, which came together in the second millennium BCE in the Punjab and the northern Ganges region and which by the first millennium had created a heterogeneous but fully integrated Indian culture and ethnicity.

—Jane R. McIntosh

some tribal regions, but languages of this family were once much more widespread in South Asia. Language borrowings indicate that Austro-Asiatic languages were already spoken in parts of South Asia into which Dravidian speakers moved in antiquity. Linguistic clues from the Rig-Veda suggest that at least one extinct Austro-Asiatic language, Para-Munda, was spoken in the Punjab and farther east. Language X, also extinct and identified from a few words, may have been spoken in the Ganges Valley by the second millen-

nium. The peoples of the Himalayan regions mainly speak Sino-Tibetan languages, related to those of East Asia. Modern relict languages suggest that there were once many more.

By the late Pleistocene, hunter-gatherers were thinly but widely spread throughout the subcontinent. Agricultural communities appeared first in the Indo-Iranian borderlands, where they raised local and West Asian plants and animals from around 7000 BCE, spreading into the Indus basin in the fourth and third millennia and intermingling with local hunter-gatherer groups, particularly in Gujarat and Punjab. From this mix a culture of villages and towns arose, developing by 2500 BCE into the Harappan civilization. This state interacted profitably with its neighbors, including hunter-gatherers, fishers, and farmers. Communities in northern South India were raising cattle and local crops; in the middle Ganges Valley foragers also exploited local and West Asian domestic plants and animals.

The Harappan state disintegrated in the early second millennium. Urban culture was abandoned, but many other aspects of life, including farming and craft production, continued and developed. Population in the Indus and Saraswati valleys declined significantly but rose in Gujarat, Rajasthan, and Madhya Pradesh, where villages and later towns grew up, spreading through the Deccan into the south and in the east, where farming villages spread gradually from the Ganges-Yamuna doab into the Ganges Valley. The earlier second millennium also saw the arrival in the north of horses, weaponry, and other new features.

Each of these lines of evidence offers some information relevant to identifying ethnicity. It is tempting to make a neat story from these in which ethnic groups are identified with archaeological cultures and linguistic groups along the following lines.

After the subcontinent was colonized by hunter-gatherers during the Pleistocene, regional groups separated by geographical barriers evolved different languages, including Austro-Asiatic languages, across much of the subcontinent and perhaps Dravidian in the west. People from East Asia, speaking an ancestral Sino-Tibetan language, settled in the eastern and Himalayan regions. Male farmers from West Asia,

bringing their crops and animals, settled in Baluchistan in the eighth millennium BCE, marrying local women. Further western settlers, possibly Dravidian speakers, arrived during the fifth millennium but had no apparent cultural impact. Population increased in Baluchistan, and in the fourth millennium its herders and farmers colonized the Indus basin, integrating some local hunter-gatherer communities and establishing mutually beneficial relations with others who continued as hunter-gatherers or took up farming. From this rich and diverse cultural, economic, ethnic, and linguistic mix developed the Harappan civilization. The Harappan state fragmented in the early second millennium, with depopulation in the central region. Farmers in Gujarat and western India expanded gradually southward, interacting with local farmers. By the late first millennium these were Dravidian speakers, implying that some earlier cultures of western and/or southern India spoke Proto-Dravidian. Farmers in the Punjab and the eastern Harappan region spread gradually into the Ganges Valley, becoming culturally, ethnically, and linguistically mixed with its inhabitants. At the same time, small numbers of outsiders were arriving in the northwest, speaking Indo-Aryan languages, conducting Vedic rituals, and using horses and chariots in cattle-rustling raids; among them were the authors of the *Rig-Veda*. After centuries of linguistic and cultural interaction, Indian-influenced Indo-Aryan languages became dominant in the Ganges basin, spreading out from there through military conquests that culminated in the Mauryan empire. By this time, however, the contribution of the original Indo-Aryan settlers to the gene pool had been infinitely diluted and the Vedic religion subsumed into the plurality of Hinduism.

This story is undoubtedly a simplification. In reality it is impossible to entirely mesh the results of the individual types of evidence since they relate to aspects of life that are independent, different, and fluid. At various times and in various places, groups must have considered themselves ethnically distinct, but at all times there were cultural, biological, and linguistic interchanges that were constantly blurring the distinctions.

The Appearance of Regional Differentiation in North America

Prior to the Archaic period, little regional differentiation between prehistoric peoples and their lifeways can be determined in North America based on the archaeological record. During the Early Archaic period it is possible to distinguish large-scale regions based on lithic point styles and/or general subsistence practices. However, it was not until about the Middle Archaic period that specific regional differences began to appear in terms of social organization, cooperative construction of large-scale structures, the development of long-term resource storage, and other lifeway patterns. Coupled with area-specific ecological factors, these processes resulted in the development of eight large-scale regions, each of which contained subregional differences: Arctic, Subarctic, Northwest Coast, California, Plateau, Great Basin, Southwest, Plains, and Eastern Woodlands. Although each of these large-scale regions can be differentiated from each other, it is important to note that regional boundaries at this time were fluid and dynamic.

For example, there is clear evidence that by 2000 BCE regional and subregional differentiation had taken place in California. However, there is also evidence of cultural continuity, indicating that the appearance of regional and subregional differentiation occurred out of local long-term processes. Common elements for all occupants of prehistoric California are found in hunting implements, with the early groups apparently equipped with the atlatl, and there is also evidence for the use of milling stones for small-seed grinding. Evidence also indicates that by 2,000 BCE native peoples had specialized in selective exploitations of particular environments, and village sites show signs of permanent housing middle-sized populations.

➤ APPEARANCE OF REGIONAL DIFFERENTIATION IN THE SOUTHWEST

Although the southwestern region of the United States was differentiated from neighboring regions by about 2000 BCE, little interregional differentiation appears to have been established. By about 550 CE, however, regional differentiation within the Southwest became apparent as lifeway patterns became more sedentary and several small-scale regional networks emerged. Based on farming-foraging economies, these regional differences are evidenced in the geographic location of settlements, the types of pottery found, and the degree to which reliance on agriculture occurred. For example, the Mogollon area differentiated itself from other areas of the Southwest region by its distinctive layout of pueblo villages focusing inward on plazas, rectangular kivas within room blocks, the three-quarter groove axe, and brown corrugated pottery often with patterned, incised, or painted designs. Furthermore, the prehistoric peoples of the Mogollon region appear to have been far less committed to agriculture than their northern and western neighbors, suggesting that adoption of agriculture played some role in regional differentiation within the Southwest.

—Peter N. Jones

Differentiating the California region from the Southwest and Great Basin regions is simple, but any attempt at drawing a precise line between the Northwest Coast region and California has proven difficult. However, it is possible to clearly differentiate the Plateau region from the Northwest Coast. Evidence indicates that by about 2000 BCE most of the Plateau lifeway pattern focused on the mass harvest and long-term storage of fish, edible roots, and large ungulates. Likewise, settlement systems by this time appear to have become relatively similar throughout the region, characterized by winter settlement in lowlands and a series of resource-harvesting forays throughout warmer seasons into the uplands or to prime fishing sites. Subsequently, around 2,500 years ago settlements appear to have contracted into large villages centered on the lower reaches of the great rivers, some with more than 100 houses. Furthermore, because

populations contracted, subregional differentiation between social groups developed, as inferred from regional rock art and burial locations and styles.

In fact, across most lands laying between the mountain ranges, or intermontane, of western North America the early Archaic lifeway patterns were similar, found over a vast area from Oregon to the central Mexican Plateau and from the flanks of the Sierra Nevada to the western slopes of the Rockies. By the Middle Archaic, however, detectable regional variations can be found in the archaeological record, primarily the result of available resources and ecologically tied processes that influenced cultural development.

On the other hand, the Plains region, beginning on the eastern flanks of the Rocky Mountains, differentiated itself from the large intermontane regions to the west much earlier. For example, around 8,000 years ago lifeway patterns on the Plains differentiated themselves from other neighboring regions. Characterized by groups of band-level size that continually fragmented and aggregated in response to food resources, especially large game such as buffalo, the prehistoric peoples during this period practiced a highly mobile hunter-gatherer subsistence lifeway pattern. Furthermore, because regional differentiation for the Plains was devised by comparison to archaeological materials of what did not develop in other regions such as the Southwest, the Northeast, or the Southeast, the prehistoric peoples of the Plains region are also characterized by the lack of sedentary lifeway patterns. The Plains were differentiated as a region based on these characteristics until the development of agriculture, and only then did the eastern Plains differentiate itself as a clear subregion.

Although there is evidence that the southern Plains and the Southwest regions shared many similar characteristics during the Early Archaic period, it is possible to clearly demarcate the two regions by the Middle Archaic period. The specific regional differences that distinguish the Southwest from other regions are permanent villages with relatively dense populations; regionally differentiated architectural forms including pithouses, jacals, and adobe and masonry structures; evidence of specialized religious and ritual

structures; patterned settlements; agriculture; pottery; and evidence for trade and exchange with other distant regions. These patterns emerged around 4,500–3,500 years ago and clearly distinguish the Southwest from the Plains and Great Basin regions, both of which maintained a more seasonally nomadic lifeway pattern, and the California region, where lifeway patterns remained constant and agriculture was not adopted to the extent that it was in the Southwest.

Regional differentiation also occurred in the Eastern Woodlands at around the same time, although subregional differentiation between the Northeast, Southeast, Great Lakes, and Mississippian regions occurred somewhat later. For example, between 2,300 and 1,500 years ago, the cultural lifeway adaptations in the Northeast underwent a change that resulted in a number of transitions, and by about 1,200 years ago the Mississippian cultures of the central Midwest were beginning to take their distinctive forms.

■ Introduction: Law

Even today in areas influenced by the European tradition, law is rooted in the advances in jurisprudence made in Mesopotamia 5,000 years ago. The Mesopotamian legal traditions provided the basis for the concepts that would later inspire the legal thought preserved in the Old Testament, which in some ways preserves the Mesopotamian traditions but in other ways significantly departs from them. Many of the key concepts and institutions in modern legal thought can be traced back to Mesopotamia.

Law does not just arise in Mesopotamia during the period from 4000 BCE to 1000 BCE. The

Egyptians also had complex notions of law, believing that there was an ideal ordering of society and that laws could be enacted to help create this ideal ordering. Legal traditions are less formalized in other regions, although conceptions of law and conflict resolution permeate the stories of Homer from Greece and the Vedic texts from India.

That formal law should first arise in this period is not surprising. In this era the first writing emerged, a necessity for the codification of law (a term that describes the results when laws of a state are collected and arranged in a systematic manner, although it is arguable whether or not

Mesopotamian law should actually be considered to be codified). The growth of urban populations meant that more strangers were living together in close proximity. These strangers relied on each other for their basic subsistence needs, security, and the satisfaction of wants. Thus, it was important that the rules that governed these various kinds of interactions be formalized. Law also reflects political and social authority beyond the level of the family; there must be a consensus among the members of the community that this body has the right (or ability if the power is coercive) to enact laws that govern the behavior of the individual.

The study of ancient law poses some interesting problems. It is very difficult to understand the relationship between various ancient “codes” of law and the actual practice of law in antiquity. The Code of Hammurabi is a good example of these problems. This text, which is frequently mistaken to be the first code of laws (it is not the first, and some say it is not even a code!) lists a series of very specific conflicts and provides the legal resolution that should be offered in each situation. The resolutions to actual ancient court cases sometimes follow Hammurabi’s precepts very closely yet at other times deviated substantially. Does this mean that some people studied the Code of Hammurabi and used it in legal decision making and that others did not? Was the Code of Hammurabi set up in a public center with the intention that it be consulted for legal crises, or was it merely a royal inscription set up as propaganda asserting that law was from the authority of the king (as opposed to other figures)? These questions are still open to debate.

—Kevin M. McGeough

Egyptian Law

Ancient Egypt did not have a fully codified system of laws in pharaonic times. The king sometimes issued decrees that constituted legal statutes, and such edicts comprise the closest thing to a law code that can be identified. The ancient Egyptian term often translated as “law” (*hep*) seems to encompass a broader array of meaning that, along with royal decrees, can include virtually any kind of rule whether applied through tradition, legal process, or contract.

These would have been predicated upon the guiding concept of justice (*maat*). In theory the king was the ultimate judicial authority; however, in practice the office of vizier customarily acted as the top legal officer. Much of the evidence relating to law and judicial practice dates to the late New Kingdom. An abundance of material derives from the village of Deir el-Medina near Thebes, the home settlement of the builders of the Valley of the Kings.

Options for addressing an alleged crime depended on the degree of the offense and the status of the injured party. Ancient Egypt did not have legal personnel corresponding to modern professional lawyers, and full-time judges are not recognized until after the New Kingdom. Councils assembled periodically to conduct trials. Individual plaintiffs and defendants were responsible for gathering evidence and presenting their own cases. The basic judicial body in ancient Egypt was called a *qenbet*, a court tribunal. A local *qenbet* was comprised of community members, especially those in high office, and sometimes visiting officials from the ranks of the royal government. It is not clear whether minimum qualifications had to be met or if some official standing was required to serve on a local *qenbet* in all cases. At Deir el-Medina regular workmen are known to have served.

Higher courts also existed in the form of great *qenbets*, such as those of Thebes in the south and Heliopolis in the north. These institutions operated under the vizier and were composed of upper-level officials from the regional or national administration, including those holding priestly titles. This echelon of the judiciary dealt with crimes against the state, including the temple system, royal foundations, and state landholdings. Cases include felonies such as treason, attempts on the life of the king (e.g., Ramses III), or looting of royal tombs in the Valley of the Kings (late Twentieth Dynasty). Sentences of extreme corporal or capital punishments—bodily mutilation (e.g., removal of ears or noses), execution, or forced suicide—were available only to the highest judicial practitioners, namely viziers and kings. Reports of the royal tomb robberies of the late New Kingdom indicate that torture was condoned as a method of questioning suspects in such important investigations.

➤ MAAT

Maat is nothing short of the guiding principle of the ancient Egyptian way of life and worldview. It was at once an ethical concept, a natural philosophy, and a goddess. Conceptually it encompasses notions of order, truth, and justice. *Maat* was present as of the creation of the universe, acting as the positive antithesis of *isfet* (disorder, chaos). The Egyptians classified aspects of the world by these two opposing concepts: whereas Egypt exemplified *maat*, foreign lands were agents of *isfet*. The inhospitable desert was an environment of *isfet*, contrasting with the ordered and habitable cultivation of the Nile Valley.

Political, social, and cosmic stability required that *maat* overcome chaos, which always threatened to throw the world into disarray. Prominent kingly responsibilities included maintaining *maat* by fostering the country through skillful administration and devotion to the gods. The gods were said to feed on *maat*, thus the scenes of the pharaoh offering it to the gods on some temple and tomb walls.

As a personified goddess, *Maat* was the daughter of the sun-god Re. She is depicted as a woman wearing a headband with a single ostrich feather. The feather often appears alone as the symbol of *maat* as both idea and deity. Its most well-known appearance is on the scale of judgment in chapter 125 of the Book of the Dead, where it is weighed against the heart of the deceased to gauge whether she or he had lived by the principles of *maat* and was thus worthy of the eternal afterlife that every Egyptian desired to achieve.

—Nicholas S. Picardo

Seated figure of the goddess Maat, personification of truth and justice, Twenty-first–Twenty-second Dynasty. (Werner Forman/Art Resource, NY)

Much evidence from ancient Egypt deals with contract law. Virtually everyone had a legal right to ownership of property regardless of social status or gender. Ideally, any arrangement dealing with land or property was recorded in writing in case of later dispute. Such documentation held considerable weight in the *qenbet*, as

did the swearing of oaths for testimony in any legal matter. Common issues brought before the local *qenbet* were breaches of contract for goods and services (such as that of a servant or a donkey), failure to honor debt, accusations of theft, and inheritance disputes. Resolution often resulted in restoration of property or fulfillment of

the contract with interest added up to full value of the original terms. Beatings could be threatened as incentive for the responsible party to pay in a timely fashion.

Theft of temple property or unlawful use of temple landholdings carried especially heavy consequences and punitive damages. A return of many times the amount stolen could be added to beatings and even death. In general, corruption of high office was distinctly frowned upon, although it is well documented. Officials guilty of crimes as well as those who knowingly failed to report criminal activity risked physical punishments, loss of professional office and status, and mandatory labor service. Repercussions could extend from the primary offender to his family as well, and monetary damages could also be levied against a criminal's descendants.

As a complement to trial in the qenbet system, judgment by oracle also became a valid procedure for settling disputes by the late New Kingdom. As documented at Deir el-Medina, an image of a patron god or goddess (in the form of a statue or the like) was carried on a portable platform before a crowd. Simple questions were put to the deity, whose simple positive or negative verdict was conveyed by specific patterns of movement. The influence of the deity's priestly porters upon the judgment is obvious, and presumably the answer would have complied with local standards of behavior or law. Whether these were the very same individuals who would have served on the local qenbet is not known, although this possibility exists.

Homeric Legal Traditions

The culture and society of ancient Greeks is thoroughly reflected in the Homeric poems of the *Iliad* and the *Odyssey*. Homer (ca. eighth century BCE) is among the most important and influential literary figures of antiquity whose writings served as a basis for ordering much of the value systems of the ancient world in terms of legal, cultural, philosophical, and societal traditions. Much of his writing emerges from the Greek Dark Ages in the eighth century BCE, which was a time of prevalent social and political disorder in the Greek world. The myths and stories that inspired the *Iliad* and the *Odyssey* further inspired Greek societies in the Classical and Hellenistic periods. Philosophers such as Plato and Aristotle discuss the value systems that they interpret from the stories in both the *Iliad* and the *Odyssey*. The intricate level of description in Homer's depictions of various characters, either gods or mortals, and their conflicts and resolutions to problems presented Greeks with a model of proper behavior, values, and ethics regarding similar problems that they might confront. Stories regarding justice and property rights had much bearing in later Greek and Roman society.

Homer's *Iliad* offers retribution as a means for resolving a wrong or offense committed against a person and his family—or acquaintances, as in the case of Achilles' duel with Hector regarding Patroclus's death. In the midst of the Trojan War, Achilles has a quarrel with King Agamemnon, both allies in the war against Sparta. His friend/cousin Patroclus beckons Achilles to let him fight using his enchanted armor. Subsequently, Patroclus is slain by the Trojan champion Hector, and his corpse is defiled. Enraged, Achilles engages in a duel to avenge this slight and kills Hector, defiling his corpse in a manner unbecoming a person of his rank. However, this serves as a case where Hector overstepped the bounds of proper rules of war and engaged in an excess that could only be resolved though an

equal act. While both acts are equally atrocious and undesirable on the part of a Greek warrior, Achilles is justified and absolved in that his action is in direct response to that of Hector's actions. This eye-for-an-eye approach represents not only the justice of the eighth-century Greek world but also the rationale that the later Classic and Hellenic Greeks would utilize in similar situations.

The *Odyssey* also contains various episodes that expressed instances of legal procedures used as precedent in later periods, such as Penelope's property rights in the absence of Odysseus. In this instance, Odysseus is absent for 20 years, having been lost at sea at the conclusion of the Trojan War, leaving his wife Penelope in possession of his properties as king in Ithaca. Penelope's position in his absence gives her command of all his properties as well as the right to remarry. In this right to remarry, she possesses the right to pass the succession of the throne of Ithaca. Therefore, various aristocratic suitors attempt to woo her in order to become king of Ithaca, not to mention to marry the beautiful Penelope. However, she stalls them for several years in order to retain the estate of Odysseus in his absence and secure it for their son Telemachus. From this story, scholars interpret that women in Archaic Greek society had a level of agency as executors of their husband's estates. Penelope's cunning in avoiding marriage illustrates that perhaps she valued this position to which she was privy due to a veritable loophole ruled by men. This episode in the *Odyssey* offers a glimpse into the daily life of the ancient Greeks and their issues over property values and gender roles.

Hittite Law

The Hittite law collections can be divided into two groups, the earlier dating to the Old Hittite Kingdom (ca. 1650-1500 BCE) and the later dating to the New Hittite Kingdom (ca. 1400-1180 BCE). Both groups are written in cuneiform, a wedge-shaped writing system, and are generally identical, though the language of the New Kingdom laws is substantially updated. Only one New Kingdom law text, the Late Parallel Text, contains actual legal revisions. The Hittite laws are part of a broader ancient Near Eastern legal tradition that includes the Sumerian Laws of Shulgi (ca. 2094 BCE), the Old Babylonian Laws of Hammurabi (ca. 1750 BCE), and the Middle Assyrian Laws of the late second millennium.

Built upon precedent and local custom, Hittite law was case law, following an "if . . . then" formula. The laws included in the collections were probably derived from specific cases that had already been tried and were not intended to be authoritative for future cases. Thus, governors and magistrates continued to follow local traditions in their decisions, often contradicting the judgments in the law collections. The king also reserved the right to decide any lawsuit directly, and his judgments were to be strictly followed under penalty of death.

The underlying principle of the Hittite laws was the accessibility of justice to all subjects, ensuring that any offenses committed against person or property could be remedied. In practice, this remedy took many forms, including corporal punishment, monetary fines, or other repayment awarded to the victim and various other forms of compensation and restitution. The Hittite ideal for compensation and restitution is exemplified in the instance in which an incapacitated assault victim received a monetary payment from the offender, who also paid for the victim's medical care and provided a worker to perform the victim's duties until he recovered. Cases of theft usually involved a punitive fine or a doubled repayment in kind, so that a man who

THE DEVELOPMENT OF HITTITE LAW

Many of the Old Hittite Kingdom laws refer to older Hittite legal precedents that have not survived, contrasting the harsh standards of long ago with more lenient contemporary rulings. For example, the corporal punishment originally prescribed for certain offenses was replaced by fines in Old Kingdom written laws. Similarly, sheep could be substituted for an offender in cases that previously demanded capital punishment. This more lenient standard of punishment continued to develop in the laws of the New Kingdom in which fines were generally reduced by half, presumably because the king now waived his fee.

—Spencer L. Allen

stole an ox not only had to return the original ox to its owner but also had to supply a second ox. Double restoration and compensation were also applied to unintentional manslaughter, so that the man who accidentally killed a free man or free woman had to both pay the burial expenses and provide the victim's household with two replacements from his own household.

Notably, Hittite law was not equal in its application. The punishments imposed upon the offender were dependent both on his or her own social status and that of the victim. Corporal punishment was primarily reserved for slaves found guilty of burglary or arson, and in assault cases where the victim was a slave, punitive fines were half those imposed in cases where the victim was a free citizen. Capital punishment was reserved for a variety of unrelated offenses: rejecting the king's judgment, black magic, certain forms of bestiality, limited forms of theft, and adultery. Capital punishment could, however, be overridden in certain circumstances. The king could reduce a sentence at his discretion, and the husband of an adulterous wife could spare her life if he also spared that of her paramour.

Mesopotamian Law

Our knowledge of Mesopotamian law comes piecemeal from law codes and court records. The law codes were collections of legal provisions set down by the king, often after he had conquered new territory where laws might be different. The earliest attested example was that of Uru-inim-gina of Lagash; others were compiled by the Ur III king Shulgi, Lipit-Ishtar of Isin, Hammurabi, and later monarchs. They include statements about a selection of cases and situations along with the appropriate action to be taken. These often followed customary law but also included reforms made by the king. Hammurabi's Code includes the harsh *lex talionis* (punishment by reciprocal injury: "an eye for an eye, a tooth for a tooth") that is often thought to have reflected the traditions of the nomadic Amorites. In contrast, earlier codes tended to prescribe more humane punishments involving compensation.

These codes are by no means comprehensive, and many recorded court judgments follow other systems, reflecting custom and tradition and the experience of the judiciary. As society changed, traditional law was modified to reflect contemporary practice and attitudes. Many of the recorded cases deal with civil matters such as inheritance, adoption, and the sale of property. Others relate to crimes: injury, manslaughter and murder, adultery, rape, theft, and criminal damage. The penalty might depend on the wishes of the victim. In the case of murder, for example, the victim's family could choose whether the murderer was to be executed or should pay them compensation.

Often courts had to deal with conflicting claims such as disputed ownership. In such cases the parties involved might be required to swear an oath on a sacred object, such as a divine emblem, with fear of committing sacrilege

constraining them from perjuring themselves. In the most serious cases, one or both litigants might be required to undergo the river ordeal to demonstrate their guilt or innocence. The selected party or parties had to plunge into a given part of the river; if they sank their guilt was established.

The judiciary operated at three levels. Local councils of elders representing a village or an urban ward dealt with everyday matters such as divorce applications, disputed paternity, and conflicts over inheritance. The members of the council made decisions based on their experience of and familiarity with the litigants and could call upon local witnesses with inside knowledge to testify under oath. Where oral testimony was unavailable, documentary evidence could also be produced, such as records of former transactions or agreements or of the outcome of pertinent earlier legal proceedings.

If the council felt unable to deal with a case or if one of the parties was dissatisfied with its outcome, the matter could be referred to a higher authority, a judge appointed by the king, or to the king himself—the highest authority. Some serious offenses such as murder, known as *din napolishtim* (“case of life”), were referred directly to the king as a matter of course, but he could send cases back to the council whose detailed local knowledge could be important in establishing or disproving guilt.

The role of the judiciary was not only to resolve disputes and punish criminal behavior but also to administer and enforce government decrees and to witness and record legally binding agreements between individuals. Most contracts were agreed upon orally, often before witnesses, and took their force from the power invested in the words of the legal formulae used, which were often backed up by performing symbolic gestures. The use of such formulae and actions in creating a legal marriage bond is familiar in modern society across the globe; in ancient Mesopotamia they were also used to legalize many other contracts, such as that between a landowner and his tenant. Written records of these transactions did not increase their legality, which was made binding by the oral pronouncements, but served as a record in case of future disputes. In the third millennium, these documents were

authenticated by an official seal; later the seals of the parties involved and of witnesses were generally required.

The Relationship between Biblical and Cuneiform Law

Historians of cuneiform law have long recognized that there was a relationship between the legal materials preserved in the Hebrew Bible (Old Testament) and ancient Mesopotamian and Hittite law. The forms in which ancient laws were preserved are similar, and many of the laws seem to reflect a shared social and legal culture throughout the ancient Near East. Thus, the study of ancient law has developed as a subfield of Near Eastern studies that brings a comparative approach to the study of Mesopotamian, Hittite, biblical, and even Egyptian literature.

The laws and legal reasoning preserved in various parts of the Hebrew Bible reflects many shared Near Eastern social norms. Many of the laws found in the Bible are very closely paralleled in other Near Eastern sources. For example, laws prohibiting sorcery, laws regarding kidnapping, and the use of false weights and measures are conceptualized similarly in the Bible and in cuneiform legal sources. Scholars have recognized that there are a number of issues that are of great concern in the Mesopotamian legal traditions that are not treated in biblical

► THE GORING OX

Ancient Near Eastern laws dealing with goring oxen well illustrate the similarities and differences between biblical and Mesopotamian law. Oxen are dangerous and powerful animals but were fundamental to the agricultural lifestyles of the Mesopotamians and the people of the Bible. Thus, numerous laws provide guidance for what to do and who has responsibility in different situations when an individual loses control of an ox. While both Mesopotamian and biblical law provide some sort of compensation for the victim, the biblical laws (as presented in Exod. 21:28–32, 35–36) also state that the ox must be punished. It must be stoned to death, and no one may eat its flesh, as it has committed a crime against the community and against God.

—Kevin M. McGeough

law. However, these issues are often dealt with in later Jewish texts (such as the Mishnah) in a manner similar to how they were dealt with in ancient Mesopotamia, which suggests that there was a shared legal milieu that was not preserved in biblical literature. So, for example, laws about what to do with wedding gifts when the husband or wife to be has died before the wedding are remarkably similar in the Code of Hammurabi and the Mishnah (which dates to the early third century CE).

There are instances where some of the biblical laws (especially the presumably older laws) reflect a more tribally oriented society and a less urban society than those of Mesopotamia. For example, crimes related to murder are treated differently in the Mesopotamian and biblical corpora. In the Bible, relatives of the victim are allowed (if not compelled) to kill the murderer or a member of the murderer's family for vengeance. This practice is usually referred to as blood vengeance and is a typical manner of dealing with murder in tribal societies. Mesopotamian laws deal with murder, often through similar punishments, but the punishments are meted out by the state.

Historians of ancient law have analyzed the literary similarities and differences between Mesopotamian and biblical law in great detail. Most

agree that while the term “code” is often used for the literary form of laws in both societies, the use of this term is somewhat erroneous, as neither collection attempts to provide complete and comprehensive overviews of the entire legal system. Both Mesopotamian and biblical legal writers articulated laws in a casuistic manner. This means that the first part of the statement of law was the presentation of a hypothetical situation, and the second part of the statement of law indicates what the punishment for that hypothetical case should be. The famous biblical scholar Albrecht Alt noted that biblical laws were also formulated as apodictic statements. The so-called Ten Commandments, for example, are apodictic laws, commands of what should not be done. Apodictic formulations are relatively uncommon in Mesopotamian law, and historians debate to what extent this is a unique biblical phenomenon.

The most significant difference between biblical law and the laws of other Near Eastern societies is in the understanding of where the authority to enact law stems from. For the ancient Mesopotamians, law was the domain of the king, and legal codes (such as the Code of Hammurabi) were written from the perspective of the king. They were understood to have been created by the king, whether or not this was actually the case. According to the Bible, the authority for biblical law came not from a secular authority but through God. As it is presented in the Hebrew Bible, laws were presented to the prophets directly by God. Thus, a transgression of law was not just a transgression against the society and king but against God as well. Some scholars have argued that this creates a different ethical obligation in the relationship between the community and the legal theory, since a transgression against God would have been conceptualized as significantly more serious than a transgression against the king.

■ Introduction: Gender

The study of gender in the period from 4000 BCE to 1000 BCE is one of the most difficult yet potentially most rewarding areas of research available to historians. The archaeological evidence to aid the study of gender is very uneven. Archaeologists can look at ancient burials; since it is frequently possible to identify the sex of the interred bodies, archaeologists can extrapolate about gender roles from the differing treatment of the different sexes in death. Art historical evidence can also inform about gender roles, since it is frequently possible to identify the sexes of the artistic subjects. The textual record from Egypt and Mesopotamia is particularly rich for the study of gender; legal texts especially provide direct evidence for ancient conceptions of gender and gender roles. Given the importance of this topic, historians frequently attempt innovative and creative methods for reconstructing ancient gender roles and norms.

The archaeology of gender should be differentiated from feminist archaeology, since these two disciplines have different goals. Feminist archaeologists are concerned with the male bias in archaeology and in the historical record. This is important work, since historical evidence has a decidedly male bias and the practice of studying history has long been dominated by males (although there have been many noteworthy female archaeologists since the development of archaeology as a scientific discipline). Gender archaeology is the attempt to study ancient conceptions of gender, ancient gender roles, and the social construction of gender. Gender is understood to be a social construction, whereas sex has a biological basis. While the terms are used differently by different scholars, generally this is a good rule of thumb. Gender scholars tend to see gender as more complex than a mere polar-

ity between male and female; it is part of a larger structure of social meaning.

This may seem like the kind of obscure theory that scholars are often accused of using to make simple reality more complex, but when studying gender in this period, it becomes clear that a simple bipolar schema is insufficient. Children are often a problem for a bipolar model, since they are usually treated as neither fully male nor female until they reach the age of puberty. Isolated instances, though, are where the boundaries between male and female really appear to be problematic. Take the Egyptian queen Hatshepsut, for example. She was a woman who became the sole leader of Egypt. In private artistic depictions of her, she is portrayed as a woman and as a mother. In public depictions, she is dressed as a man and wears a false beard, one of the Egyptian symbols of kingship. Ancient graffiti of Hatshepsut depicts her in various sexual positions and was likely intended to be derogatory. Since this type of graffiti is not found for the male kings of Egypt, it seems that Hatshepsut's gender was the subject of public discourse in ancient Egypt.

—Kevin M. McGeough

Gender in Ancient Egypt

Conceptions of gender affected the creation of the sources that are now used to study ancient Egypt, and they are also relevant to the interpretation of these sources today. Whereas biological sex (female/male/hermaphroditic) is often regarded as incontrovertible fact, gender (feminine/masculine/androgynous) is constructed and negotiated by culture and custom. Although often based on dominant cultural views about biological sex and prescribed roles in life, concepts of gender are malleable. Much of the surviving

➤ SEXUAL IDENTITY AND DISCOURAGED SEXUALITY IN ANCIENT EGYPT

Although sex and sexuality are rarely addressed directly by ancient Egyptian sources, it is abundantly clear that notions of femininity and masculinity correspond directly to fertility and virility, respectively. In one of the primary ancient Egyptian accounts of creation, the initial ordering of the universe by the creator god Re-Atum began with the asexual release of bodily fluid (the precise fluid varies by version of the myth). However, the rest of creation proceeded through the union of male and female consorts. The gods themselves were aligned as family groups, usually triads consisting of parents and an offspring. This family unit was a cornerstone of ancient Egyptian culture. For both the divine and the mortal, the cycles of birth-life-death-rebirth pervade the Egyptian understanding of the world, with procreation as an integral element of the process. Homosexuality, which was inconsistent with the procreative ideal of this dominant cultural view, was thus generally frowned upon.

An assortment of relevant documents refers only to male homosexuality. In the popular *Tale of King Neferkare and General Saset*, a king, possibly Pepy II, is said to have amorous nighttime liaisons with his general, whose unmarried status is emphasized. At least one character finds this

situation objectionable. A missing ending makes it unclear if the story concludes with an obvious moral statement about homosexuality. In the Late Egyptian mythological story *The Contendings of Horus and Seth*, the chaotic god Seth attempts to establish himself as the sexual conqueror of Horus as a means of proving dominance over him. Through a crafty ruse the tables are turned, however, and Horus is revealed as the sexual superior. It also suggests that sexual roles were linked to issues of power and dominance.

Perhaps because of such religious underpinnings, the Book of the Dead contains a passage in which a deceased Egyptian disavows homosexual experience as this might prevent successful admission into the afterlife. However, inclusion of homosexuality in this context is also perhaps the clearest attestation that it was an acknowledged reality in ancient times. The earliest of these sources, *The Maxims of Ptahhotep*, warns against sexual encounters with an especially effeminate male. In total, these sources suggest that the main objection to male homosexuality was that someone acted in a feminine role but lacked the female fertility to fulfill the procreative norm prescribed by ancient Egyptian culture.

—Nicholas S. Picardo

evidence reflects the elite perspective, and as with most ancient Egyptian material, the loudest voice is male. Additionally, there is ample reason to expect that gender roles were not entirely consistent through all levels of society.

As illustrated by the hieroglyphic writing system, the ancient Egyptians acknowledged two gender categories: masculine and feminine. Most generally, gender roles revolved around the ideal of the nuclear family. Young men and women were to establish a household by marrying and starting a family at their earliest feasible opportunity. It seems to have been regarded as a responsibility of women to bear children. Sons were desired in particular, although Egyptians appear to have been enthusiastic about childbirth regardless of the sex of the child. An eldest son was called the Staff of Old Age, for he held the responsibility to care for the parents in their

advanced years. Upon his parents' deaths he was also expected to officiate the Opening of the Mouth Ceremony, the most important funerary rite. Also at the funeral, female family members acted as mourners, a role important enough by the New Kingdom that professionals could be hired.

The title that conveyed the married status of a woman was lady/mistress of the house. Egyptian society acknowledged the home as the domain of the wife, to whom household matters were often deferred. At all tiers of society a man might have to travel for work, leaving his home for lengthy periods. Even under normal circumstances, though, Egyptian mothers were required to balance the numerous responsibilities of child care and household management. If tomb scenes and models represent reality, a division of labor in the basic tasks of everyday life was rarely or-

ganized exclusively along gender lines. Provisioning of the house could involve both husband and wife, depending on the individual situation. Women of lower rank in particular may have assisted with agricultural field work, although apparently not with the most laborious cultivation tasks. However, although both sexes appear as bakers, women are more frequent, and the tedious process of stone-grinding grain appears to have been adopted specifically by women. Men align more closely with the related process of brewing beer, the staple Egyptian beverage. The weaving of linens and textiles is also one of the few occupations in which men did not participate. Both men and women comprised the servant staff for the wealthy.

The administrative system of the Egyptian state operated for and to the benefit of men, a situation that affected the opportunities of women in several ways. The socioeconomic status of a woman was dependent upon the male head of the household in which she resided, her father prior to marriage and her husband thereafter. A man's professional office was passed on through his sons; however, there are scattered examples of women holding administrative titles of significance. Because literacy was a job-specific skill, likely rather few women outside those of the highest ranks learned to read. Most positions commonly held by women were in the temple cults. Although female priestly titles appear during some time periods, women were most often musicians or chantresses who accompanied priests as they tended to daily temple rituals. Women of all social standing and profession technically had legal standing, allowing them to hold, transfer, and inherit property and land as well as enter into legal proceedings. However, the extent to which these rights were exercised in practice may have been influenced by family.

The highest office in the land, that of the king, was undisputedly a masculine role. The few cases of female pharaohs usually resulted from the absence of a suitable male heir to the throne. All signs indicate that the female Pharaoh Hatshepsut of the Eighteenth Dynasty was a capable and accomplished ruler. She obviously recognized the gender associations of kingship, in some scenes having herself depicted in male garb and with a masculine writing of her name.

Yet public response was likely far from entirely positive, as perhaps reflected by some extremely disrespectful graffiti left near her mortuary monument at Deir el-Bahri. Following her exit from the historical record, her stepson and co-regent Thutmose III embarked upon a program to destroy, alter, or conceal her monuments and erase her from historical memory.

Artistic depictions on tomb walls and stelae incorporate gender distinctions. Most superficially colored conventions distinguish between reddish-brown men and drab yellowish women. Females occupy secondary positions to men in both word and space. The primary male figure is also the primary actor of a scene, with a woman (usually his wife) watching from aside. Texts focus on his life, his work, and his titles. Women and children customarily receive labels that do not indicate their own standing; rather, their identity in this context is defined solely by their relationship to the primary male figure. Afterlife expectations on the part of women paralleled those of men. This inequality results partly from circumstance, as a tomb sizable enough to carry imagery and inscriptions was possible largely due to the husband's professional status, which was thought worthy of advertisement. That a streak of misogyny was present, however, is reflected by Egyptian literature, produced exclusively by men. Several literary stories include the character type of the temptress, and the notion of women as the primary instigators of adultery turns up in several kinds of Egyptian texts.

Cosmetics were an integral part of daily life in ancient Egypt. Almost every person, regardless of status or gender, was buried with a makeup kit. The most popular makeup was *kohl*, used around the eyes by both men and women. Usually applied around the upper and lower lash lines, although sometimes on the upper lid, kohl came in green and black colors. Kohl was not only considered a beauty aid but was also medicinal, as many prescriptions use kohl in curing eye infections. Perfumed oils were also used by both genders. They acted as deodorants, skin moisturizers, and perhaps even insect repellents as well as giving the wearer a pleasant scent. Some of the items included in perfumes were water lilies, cedar wood, herbs, and spices such as cinnamon. During the New Kingdom, banquet scenes show people with cones of perfumed fat balanced on their heads. As the perfumed cones melted, the fat dripped through the hair, nourishing it and also cooling the wearer during the hot festivities.

Egyptian Concepts of Beauty

Ancient Egyptian concepts of beauty are not easily understood, but literature, art, and artifactual remains all give clues as to what beauty involved. The concept of *maat* (truth, world order, and cosmic balance) is central to the Egyptian way of life. Evil things, acts, or people could upset the balance and allow chaos to reign. Therefore, it was every Egyptian’s duty to maintain *maat* by adhering to a moral code, worshipping the gods, obeying the king, and striving for perfection. In ancient Egyptian the same word is used for “perfect” and “beautiful,” indicating that beauty was an important facet of Egyptian life.

In literature, love poetry includes descriptions of the beauty of both men and women. Wisdom literature warns the reader to beware of beautiful women because they can lead to jealousy and because beauty may not indicate purity of heart. Fables tell of women falling in love with beautiful young men. Medical texts are full of prescriptions for wrinkle creams and cures for baldness.

The uniformity of depictions of the human figure from ancient Egyptian art throughout its long history give the best understanding as to what the Egyptians thought was beautiful. Art for the Egyptians was reality: if it was drawn or sculpted it could be magically brought to life to act as a vessel for a dead person’s spirit. Depictions of evil acts or evil people might cause them to become reality, which would threaten *maat*, or the peace and order of Egypt. To counteract this, Egyptian art rarely depicts bad actions or bad people unless they were happening to the enemy or foreigners. The result was to portray both men and women in an idealized form. Pharaohs never aged, and, in fact, few people are ever shown as being old. Youth and perfect figures dominate all of pharaonic art. Men are shown with wide shoulders, a narrow waist, slightly muscular arms and legs, reddish skin, and black

hair. Women are depicted as slim with a long neck; narrow shoulders; small, firm breasts; a small waist; pale, usually yellow, skin; and dark hair. The choices of yellow skin for women and red skin for men have a basis in reality and mythology. Because upper-class women spent most of their time indoors attending to the house, their skin was paler than the men, who spent more time outside under the hot Egyptian sun. Hathor, the goddess of beauty, fertility, and childbirth (among many other things), is described as having skin of gold. Depictions of women with yellow skin may be an emulation of the goddess of beauty.

Aberrations from the ideal form in art do exist but usually in conjunction with depictions of lower-status people, or servants, who are engaged in physical labor. In these instances, people are shown as being old or bald or with medical conditions (withered limbs, hernias, blindness). Noblemen are sometimes shown as old and portly as a way of indicating both their achievement of rank and their wisdom. Egyptian women, however, are almost never shown as fat, pregnant, old, or in poor health. Exceptions come from the Amarna period (1370–1350 BC) when the aesthetics of Egyptian art changed drastically in conjunction with changes in religion and kingship. Figures from the Amarna period are portrayed with very angular faces, almost pointed heads, very long necks, very long fingers, a small belly, rounded thighs and buttocks, and no muscle tone. Depictions of people, including women, from this period are more likely to include wrinkles and other nonidealized characteristics. Perhaps the most famous depiction of an antithesis of beauty from the pharaonic period is that of the Queen of Punt from the temple of Hatshepsut at Deir el Bahri. The queen is portrayed as obese, with rolls of fat covering her stomach, arms, and legs and with very large buttocks. Because the Queen of Punt is a foreigner and therefore does not threaten the ideals of *maat*, artists could depict the reality of her body.

The Authority of the Father and Gender Roles in Ancient Mesopotamia

The family was the cornerstone of Mesopotamian society; the male head of the household made all important family decisions. As long as he was alive, his parental authority was legally uncontested. If he so wished he could use any member of his family as collateral to secure a loan, and if he fell into debt he could sell or give his wife or children to his creditor to satisfy an outstanding obligation. Later, if financially able, he might redeem his family members, but he was under no legal or societal obligation to do so.

Children were required to obey their father's command. According to the Laws of Hammurabi no. 195, "If a son strikes his father, they shall cut off his hand." The father had the responsibility of caring for his children and could not disinherit a son without good cause. This is reflected in law numbers 168 and 169 of the Laws of Hammurabi. Law 168 reads:

"If a man should decide to disinherit his son and declares to the judges, 'I will disinherit my son,' the judges shall investigate his case and if the son is not guilty of a grave offense deserving the penalty of disinheritance, the father may not disinherit his son."

Law 169 reads:

"If he [the son] should be guilty of a grave offense deserving the penalty of disinheritance by his father, they shall pardon him for his first one; if he should commit a

grave offense a second time, the father may disinherit his son.”

Family members took the name of the father. Sons and daughters were known by their personal name followed by the name of their father. In the middle of the second millennium, a patronymic (family name) was added so that a son was called Mr. So-and-So son of Father’s Name, descendant of a named ancestor. Household slaves did not take the name of the head of the family. They were only known by their personal names without any parentage being given.

Children were grouped according to age. The youngest was called weaned at the breast. Later the child was referred to as “weaned.” A boy, once he passed adolescence and reached age 13, was considered to be an adult. He was now supposed to get married in order to “build his house.” An older adult past the age of 80 was called “aged,” and one who lived to age 90 was one of “extreme old age.” It was believed that the maximum age limit was 120.

Married women were expected to remain at home and manage their household, but they could leave the house to attend festivals or engage in household-related errands. Literary texts and art identify a married woman with a toggle pin (to hold up her garment) and a spindle. A man was associated with his weapon. Both men’s and women’s outer clothing consisted of a long one-piece garment. Women wore it pinned on the left, men on the right. Men, unless they were eunuchs or involved in religious ceremonies, grew beards, which were associated with virility. Women were considered to be unclean during their menstrual period. If a man touched a woman during menstruation, he too was declared unclean. A husband had the right to beat his wife for certain offenses. In middle Assyrian society a husband could punish his wife in a number of ways, such as cutting off her ears and nose or by beating and whipping her and pulling out her hair. Adultery was condemned. A proverb stated that “He who has intercourse with [another] man’s wife, his sin is severe.” Another proverb warns a man not to be alone in a room with someone else’s wife.

A man usually married only one woman; his wealth and name would normally be passed to

his eldest son. If, however, his wife became ill and could not bear children, then he had the right to take a second wife. This is reflected in law no. 148 of the Laws of Hammurabi, which reads:

“When a man marries a woman and she is seized with *li’bu* disease [and cannot conceive], if he has made up his mind to marry another, he may marry [her], without divorcing his ill [first] wife; she shall live in the house which he built and he shall continue to support her as long as she lives.”

If a man had no male offspring, “his hearth has been extinguished.” Many children died at childbirth or at a young age. In Assyrian society (northern Mesopotamia), abortion was deplored. A Middle Assyrian law refers to a woman who intentionally aborted her own unborn child and disposed of the fetus without burial. She was condemned to die, impaled on a stake without burial. Her ghost was doomed to wander forever, never to reach its eternal dwelling. Children were abandoned in the street, in wells, and in open areas. If saved, they could be named “He who was snatched from the mouth of a dog.” A school text refers to a child saved from the mouth of a raven.

If a couple was childless, the husband could adopt a child in lieu of taking a second wife. The primary method of adoption was to obtain a newborn infant. This was expressed by the Babylonian phrase “to take for sonship” a baby that was still “in [its] water and blood.” This later expression indicates that the baby was adopted just after birth from parents who planned to abandon the child. According to the Laws of Hammurabi no. 186, if a child became lost and was then found and raised by his adoptive family and afterward sought to locate his biological parents, that child may be reclaimed and returned to his original home. Children were also adopted into families where they would be taught the family trade. In these cases it may be assumed that the family that gives up their son was too poor to provide him with an education. The terms of this type of adoption specified that the child was to be raised and apprenticed in a craft. Such training ensured both that the boy had a profession

and that he also had a skill that could be passed on to his heirs. Failure to teach the child a craft was considered a breach of contract. When a family fell into financial straits, their children could be put up for adoption for a price equal to their cost of raising and feeding the child. The adopter, frequently a relative, purchased the child for an agreed-upon price. In special circumstances a brother might adopt and thereby legitimize his sister's illegitimate child if he considered the mother's lifestyle and living conditions to be unsuitable. Adoption was primarily a process to ensure that upper-class families had both old-age support and an heir to carry on the family name and fortune. The law supported this concept by requiring that adopted sons be considered natural heirs. If a childless couple adopted a son, he was to be their heir. If later they had biological children, the adoptee was still to be considered the eldest child and primary heir.

Women in Mesopotamia

On marriage a girl became part of her husband's household, her fate intimately tied up with his fortunes. If things went badly, she and her children could be hired out to work, and in extreme financial trouble they could be pledged as slaves against unpaid debts. A wife's dowry property was managed by her husband, and in some periods and regions she was confined to the house. Royal Assyrian ladies, from the Middle Assyrian period onward, were segregated in a harem, seeing only their husbands, children, and female attendants. In this hothouse environment, rivalry and quarrels were common. Some relief from the monotony came when the court traveled as they accompanied the king. Apart from nomads,

however, and itinerant entertainers, such as jugglers and acrobats, Mesopotamian women rarely traveled.

On the other hand, women often enjoyed considerable responsibility, running large establishments, deputizing for their absent husbands, and owning property in their own right. They could bring court cases and be called as witnesses. The Mari letters include several from Queen Shibtu to her husband Zimri-Lim about the palace administration—managing and acquiring stores, running the workshops, deploying new slaves, observing religious rites—as well as discussing personal matters. Her contemporary Iltani, queen of Karana, had to deal in addition with legal cases and petitioners on behalf of her husband. Even the Assyrian royal ladies in their harem could wield considerable political power as advisor to the king (their husband or son). On occasion their authority was overtly acknowledged; for example, the ninth-century queen Sammuramat was named in inscriptions alongside her son Adad-Nirari III. The wives of the Assur merchants who lived in Kanesh also shouldered business responsibilities, often running the Assur end of operations: supervising the textile workshops staffed by slave girls, dispatching consignments of textiles, keeping their husbands informed about the situation in Assur, handling financial matters, and, when necessary, selling off their jewelry—gold earrings, silver bracelets, and rings—to raise capital.

As brides were generally younger than their husbands, many women were widowed while their children were still young. Women in this situation often enjoyed the same business rights as men, managing the family's property on behalf of their sons. The Nuzi archives show the successful and sometimes aggressive business dealings of several such women who managed and acquired land and engaged in trade.

An exceptional group was the well-born girls dedicated to the service of Shamash in Sippar, and other gods elsewhere, as *naditum* priestesses. One of the girls' main tasks was to ensure through prayers that the deity was kept aware of their families' interests. Perhaps equally important, however, was the disposal of property, for the dowry that the girl brought to the temple cloister (*gagum*) generally reverted to the family

on her death. In return, the naditum could expect to be supported by her father or brothers. She exercised full control over her dowry lands and their revenue during her lifetime, often using the income to buy and sell goods and land and acting as a shrewd and vigorous businesswoman.

The sexual status of naditum women varied. Those in Nippur were vowed to celibacy, but the Sippar ladies could, it seems, take lovers, raising children who were adopted by their brothers, again ensuring that the dowry lands stayed within the family. In Babylon, in contrast, Marduk's naditum ladies were allowed to marry but had to remain celibate, often introducing a real or fictional younger sister as a subordinate wife to furnish the marital bed.

At the opposite end of the social scale were women whose families owned no property and who worked for a living, many of them in the woolen textile industry, especially in Babylonia where great cities such as Ur had enormous factories employing hundreds or even thousands of women and children. Although their main occupation was weaving, they might be required to undertake a variety of other tasks, including agricultural work. Large palace or temple kitchens also employed many female staff in such tasks as grinding grain; making bread, cakes, and beer; and preparing and cooking various dishes. Central to the life of every married woman, however, was the bearing and raising of children.

Gender in the Indus Valley

Since we are still unable to read the writing of the ancient inhabitants of the Indus Valley (the Harappans), reconstructing gender roles can be quite difficult. This leaves the art historical record as the main resource for the study of ancient gender. For reconstructing gender among the Harappans, the most useful resources are the numerous figurines that are recovered from sites. Usually archaeologists are able to identify figurines as male and female and thus can extrapolate about the different fashions and activities of Harappan men and women. Unfortunately, we do not really understand what these figurines were used for in ancient times (whether they were children's toys, religious artifacts, or perhaps decorative objects), so care must be taken in drawing conclusions about Indus Valley society as a whole. Imagine using a Barbie Doll and a depiction of the Virgin Mary to reconstruct modern North American society; certainly these pieces of evidence could inform you about gen-

Bronze statuette of a dancing woman from Mohenjo-daro, about 2500 BCE. (Scala/Art Resource, NY)

der roles in North America, but they would not give you a particularly balanced view.

The clearest evidence for gender difference in the Indus Valley is in regard to hairstyle. Women's hairstyles as depicted in figurines could be quite elaborate. Archaeologists have been able to identify styles that were in fashion in specific cities, indicating that we should consider fashion on a local level. The most elaborate hairstyles for women had the hair rolled and lifted above the head, with various types of jewelry inserted among the curls. This type of hairstyle would have required a hairstylist's help (it would be impossible to do this on one's own) and would have required very careful upkeep. Likely this type of hairstyle would have been limited to elite women or special occasions. Less elaborate styles still involve complex braiding, worn up or down. Women also wore head coverings, either headdresses that were incorporated into the hair or turbans that fully covered the head. Men's hairstyles show less variation. When the hair is not covered by a turban, it is worn twisted into a bun (or double bun) at the back of the head. Most male figurines have beards, but the beard was worn in a variety of styles. Both men and women would sometimes wear their hair long, especially with a long braid hanging down one side of the head.

It is more difficult to reconstruct clothing styles. Generally, male figurines are nude and female figurines wear a short skirt, which indicates a difference in sensibility toward male and female modesty. Male figurines, when dressed, wore generally one of two outfits. A long shawl may have been draped over the left shoulder and draped around the midsection like a toga. Or a piece of cloth may have been wrapped around the midsection and then tucked through the legs and into the back of the garment. Both men and women wore jewelry, but women wore larger quantities and more elaborate styles (at least in the figurines). Bangles were most common, but necklaces and rings were also common.

Most figurines depict men and women in rigid formal stances, devoid of activity. However, figurines that do depict activities can also tell us what types of work men and women engaged in. Dancing was a common subject of figurines for both men and women. In some figurines men

➤ GENDER AND BURIAL AT HARAPPA

Archaeologists working at the site of Harappa have begun trying to use genetic evidence to understand gender roles in the Indus Valley. By studying the genetic remains of bodies exhumed from ancient cemeteries, scholars have made the preliminary observation that women tended to have been buried in close proximity to their blood relatives, whereas men were not. This kind of burial practice is called *matrifocal* and suggests that after marriage women retained close ties to their own family and that men gained close ties to their in-laws.

—Kevin M. McGeough

appear to be hunting or fighting (the difference is hard to distinguish). Women are sometimes depicted as grinding grain or engaging in other aspects of food production.

Gender Roles in Vedic Society

The Vedas, dated between 1000 BCE and 300 BCE, are the most ancient religious texts from the Indian subcontinent. They consist of four books: Rig-Veda, Samaveda, Yajurveda, and Atharvaveda. These texts consist of hymns and incantations to be used during fire sacrifices to the Vedic deities. The texts themselves also give insight into the culture and society from which they were composed. One of the most interesting components of the Vedic society is the gender roles found latent within the text. Through analysis of the scriptures, this period is perceived to mute the gender separation that later periods within the region seem to emphasize. The gender roles of both males and females are most evident within the institutions of education, betrothal, and marriage.

The Vedic period was a time of great freedom for women. The age of the Vedas is rivaled only by modern times in terms of the opportunities that women, unmarried women in particular,

had to lead meaningful lives by their own merit. The opportunities were multiplied by their access to education. In Rig-Veda chapters one and ten, learned female rishis “composed verses, performed sacrifices, offered hymns to the Gods, and won glory and fame.” A major prerequisite for this ability to perform acts that would later be denied to women would be their education and initiation by the *brahmanacarya* (the vow of priestly study given by someone who has already been through the vow of study). In fact, according to the Atharvaveda, “a young daughter after the observance of *brahmanacarya* should be married.” This indicates that in fact all unmarried women should be initiated into studies before advancing into any other stage of life. It also seems as though the procurement of a “learned” husband was directly dependent on being a “learned” woman. Therefore, the education of an unmarried woman was the means by which she was able to attain personal achievements and have a good marriage. A woman’s education was the only beginning point to a successful life and thus was duly stressed in scripture.

Initiation into the education of Sanskrit and the Vedas through *brahmanacarya* was considered *dharmā* or the duty of all twice-born males, that is, males of the upper three *varnas* or castes: Brahmin, Ksatriya, and Vaisha. In fact, after the Vedic period these were the only groups allowed to enter this celibate student stage. This tradition has continued even until the present in many orthodox Hindu sects. Thus, the educational system, like at no other time until the modern secularization of India, was equally open despite gender.

During the Vedic age, women enjoyed the ability to freely choose their husbands and if they found no adequate suitor to remain unmarried. As was the case in most ancient societies that placed a heavy importance on progeny and descendents, remaining unmarried was not viewed as the most honorific position for a female. Therefore, women would at times more actively pursue their love interests and curse their rivals in love. As has already been alluded to, there had to be present the mutual consent of both the future bride and groom. This mutual consent was gained through encounters with the opposite sex such as in the Mahavrata rituals,

which can be described as orgies. There were also other rituals and festivals (called *samanas*) in which there was an intermingling of sexes. These were popular festivities in which women could enjoy themselves and seek to find a husband. Such events were necessary to bring together the opposite genders to facilitate meeting opportunities, as these were quite scarce due to daily responsibilities maintaining the home.

In the Vedic period both genders were involved in the selection of a potential suitor. This led to what is called in the Laws of Manu a “love marriage.” This is contrasted with the Epic model of Rama and Sita, where Sita is won by Rama after a display of strength and with the *dharmashastras*, which implemented the arrangement of marriage between the parents of eligible families dependent on caste. Therefore, greater interaction between the sexes prior to marriage was prevalent in this period.

Marriage was a time that stressed the difference between the roles of male and female. This was one of the most restrictive stages in the lives of Vedic women. During married life, the husband was to be worshipped as a *deva*, or god. He was in charge of the fire sacrifice and thus had a monopoly over communicating with the devas. This would ultimately lead to the widening gap between the genders during the Epic period in India. Women within the confines of marriage were even limited in their legal status. They were completely under the control of their husbands. They were also not the heirs of their property, as their eldest sons held that honor. If there was no son the husband’s brother would receive the widow into his family. He would then take over the inheritance. The wife did, however, have certain control over the household, with the children, servants, and livestock falling under her charge. She also had the duty of keeping the sacrificial fire lit. This was the same fire that was circled during the wedding ceremony that was to remain forever lit. She also had responsibility over the children, but her authority over anything was never secure because she was under the all-encompassing charge of her husband.

Therefore, the Vedic period on many levels was a time of equality between male and female. But the disparity between the two within the marital relationship would be exacerbated in the

following millennia to all but erase much of the gender equality found within the Vedas.

Nüwa and the Repair of the Broken Sky

Though the notable myth about Nüwa mending the broken sky is sometimes attributed to flood myth systems, the disaster it describes is actually not only a flood. Rather, it is a cosmic catastrophe. In some versions, this calamity was caused by the collapse of the four poles supporting heaven. In other texts, this cosmic disorder was caused by the breakdown of one of the sky poles, Mount Buzhou (literally means "not full"), in a war between the gods Gonggong and Zhuanxu (names differ in different texts). Gonggong fought with Zhuanxu to be the supreme god but failed in the war. He was so angry that he butted into Mount Buzhou.

The collapse of the sky pillar(s) caused great disasters. Fires raged fiercely and could not be extinguished. Water flowed without abating. Ferocious birds and beasts seized and devoured people. At this moment, the goddess Nüwa melted stones of five different colors to patch heaven, and cut the legs off of a huge tortoise and set them up to support the four extremities of heaven. She defeated the fierce Black Dragon to save the people, and collected ashes of reeds

to stop the flood. Her arduous work cleared up the terrible mess and put the world in order again. In some versions collected in the twentieth century, Nüwa not only mended the broken sky but also repaired the broken earth that was damaged in the same disaster. Her mythical actions often serve as an etiology to explain why people today can see colorful clouds in heaven (because the goddess mended heaven with colorful stones), and why the current western land of China is high while the east is low (she used the longer legs of the tortoise to support the west, using the shorter legs to support the east).

Homosexuality and Transgender in the Ancient Near East

No evidence has been found that people in the ancient Near East defined themselves by their sexual preferences or behavior, and no clearly attested terms define someone as heterosexual or homosexual, so it may be anachronistic to look for evidence for self-defining homosexuals in the ancient Near East. Yet there is evidence that sexual preferences were varied in antiquity as they are in the present. There are some recorded instances of what appear to be same-sex relationships, and there are references to homosexual activities in a variety of sources.

Mesopotamian legal literature contains clear allusions to male homosexual activity. Mostly these are legal proscriptions against male-male sexual activity or limitations on accusations that

➤ THE TOMB OF THE TWO BROTHERS AT SAQQARA

Relief of Nyankhkhnum and Khnumhotep from a tomb at Saqqara, Egypt, Fifth Dynasty. (Jon Bodsworth/The Egypt Archive)

An Egyptian tomb found at Saqqara, dating to the Fifth Dynasty, may have been the final resting place for two men who were partners in a same-sex relationship (in addition to their relationship with their wives). The two men, Nyankhkhnum and Khnumhotep, were wealthy workers in the royal court, both holding the title of king's manicurist. Reliefs from the tomb depict the men with their families in some areas. However, the most space is devoted to images depicting the two men together in various states of embrace. In Egyptian art, these intimate scenes are not meant to depict sexual activities but rather are intended to be illustrative of the nature of the relationship. Poses such as these are more typically used to depict relationships between husbands and wives or between kings and the gods. One theory is that these two individuals were brothers (possibly twin brothers), and generally scholars call this The Tomb of the Two Brothers. The question of whether Nyankhkhnum and Khnumhotep were friends, brothers, or lovers cannot be resolved.

—Kevin M. McGeough

can be made against men regarding their sexual practices. For example, Middle Assyrian laws (which originally date to the fourteenth century BCE but survive only in eleventh-century BCE copies) proscribe that an individual proven to have sodomized another shall be punished by being sodomized himself and then have his genitalia removed. A man who accuses another man of sodomy but cannot prove it should be punished through a physical beating, a head shaving, forced labor for the king, and a very hefty fine. The punishment is severe, not for the particular type of slander he has levied at his fellow citizen but in keeping with other penalties for those who provide false testimony.

The *Epic of Gilgamesh* (from ancient legends recorded in the seventh century BCE) is often cited as an ancient story with strong homoerotic overtones. In fact, these readings of Gilgamesh are far from certain. The hero, Gilgamesh, is described as having a voracious sexual appetite, enjoying the company of women and possibly young men. Gilgamesh's relationship with his friend Enkidu is described as very intimate, but it is not clear if a sexual relationship existed even though there are frequent double entendres describing their relationship. The scholar Martti Nissinen suggests that the relationship between Gilgamesh and Enkidu is better understood as homosocial, a strong friendship between members of the same sex.

The Egyptian Book of the Dead, a book that was buried along with the deceased in New Kingdom times to be used as a guide for passing into the afterlife, contains some hints that male homosexual practices were looked upon negatively. One section of the guide gives instructions that the deceased should assert that he has not engaged in sodomy. Egyptian literary references to male homosexual activities are explicit. In The Tale of King Neferkare and the Military Commander Saset, the king and his commander carry on a sexual relationship under the cover of night. Here, the relationship is described as mutually desired but nevertheless scandalous because of its deviation from Egyptian normative practices. In The Tale of Horus and Seth, the god Seth attempts to have intercourse with Horus both as a means of pleasuring himself and humiliating Horus.

Different moral evaluations are identifiable in the historical record for the active and passive members of a male on male sexual relationship. Some textual references suggest that there was no stigma associated with the active partner but that there was a stigma against the passive recipient of a male sexual act. For example, the Egyptian word *nkḳw* is used as an insulting term referring to a male as a recipient of a sexual act. In some Mesopotamian dream omen texts (texts that describe what particular dreams tell about the future), different male homosexual acts correspond with different forecasts for the future for the individual. For example, a man who dreams that he is the active participant in a sexual activity with another male of the same social class is actually forecasting his own development as a leader in the waking world.

From earliest Mesopotamian times until the conquest of the land by the Persians, there is evidence that certain transgendered individuals were associated with the worship of the goddess Ishtar. A transgendered individual is someone whose self-identified gender is different from their culturally assigned gender. Gender identity is different from sexual orientation, and the two issues should not be confused when researching their manifestations in the ancient world. These transgendered devotees of Ishtar were almost ex-

clusively males who had taken on traits that were deemed feminine by Mesopotamian society. Certainly this involved dressing as a woman and acting as a woman in the cultic settings. It is unclear if it involved any medical procedures, such as castration. Other evidence for transgender in the ancient Near East is more ambiguous, and there is little evidence to suggest that eunuchs were prominent within the society despite frequent statements to the contrary.

■ Introduction: Education

Education for most of the people who lived during this age (4000 to 1000 BCE) would have come primarily from their families. This education would not have been very formal but instead was a matter of learning necessary skills as the need developed. This kind of education through practice tends to be very conservative, since it perpetuates traditional methods of understanding the world and working within it.

While the family may have been the dominant educational institution at this time, it was the period in which the first schools were formed. Evidence for schools is primarily found in the Near East; the possibility that schools may have

existed in other regions of the world cannot be ruled out. These schools would not have been for as broad ranging of an education as students receive now. These schools were designed to teach specific skills to a select group of students. An education would not have been necessary for everybody (as it is today). Scribal schools were the most common types of educational institution; these were schools where students learned how to read and write, usually specializing in specific genres. Many of the copies of Mesopotamian literature that have survived to the present day are actually school exercise tablets, the remnants of an ancient student's homework now

used to reconstruct the lost literary heritage of an ancient society.

The development of the school as a medium for education is indicative of larger changes in society as a whole. It reflects a sensibility that the community at large should play a part in the education of some individuals. The community could set standards not only about who could get this knowledge but what constituted knowledge that needed to be taught. The development of schools is also indicative of a more complex society. The need for schools reflects that more specialized types of knowledge had developed (such as writing), knowledge that could not just be picked up “on the job.”

—Kevin M. McGeough

Egyptian Scribal Academies

The scribal profession was the cornerstone of ancient Egypt’s civil and military administration from the earliest dynasties through the end of pharaonic history. Although the basic designation of *sešb* (scribe) was not a particularly high-ranking title, having a scribe’s education was a necessary prerequisite for advancement in the bureaucracy. One of the most telling pieces of

archaeological evidence for the prestige accorded to scribes comes from the many scribal statues placed on behalf of deceased individuals in tombs and temples. These figures are shown seated with legs crossed, a papyrus unrolled in the lap, and writing utensil in hand. Even officials whose rank far outstripped that of a mere scribe frequently chose to have themselves depicted in this fashion, clearly demonstrating the high premium placed on literacy by the largely illiterate society.

The literacy rate in ancient Egypt was, as a rule, probably less than 2 percent in any given period. Consequently, education at scribal academies must have remained the prerogative of a relatively small cross-section of elite males. It is therefore hardly surprising that scribal training often appears to have acquired the character of a hereditary prerogative, passed from father to son. Private correspondence in the New Kingdom, much of which derives from the unusually literate workmen’s village of Deir el-Medina, also attests to the presence of literate women. However, textual evidence for formally trained female scribes is sparse and often inconclusive.

Formal studies at a scribal school (*at ni seba*, or “room of instruction”) began with training in the script and in grammar, elementary mathematics, geometry, etc., lasting around four years. Junior scribes did not begin their studies with the monumental hieroglyphic script. Rather, the cursive hieratic script used for administrative purposes, record keeping, correspondence, etc., was taught first. Many schoolboys’ copies of practice texts, written in ink on potsherds or flakes of limestone, known as ostraca, attest to the countless hours of copying and recopying of basic texts required at the early stages of a scribe’s education. Onomastica—encyclopedia lists naming different classes of objects—were one type of text used for this purpose. Later, the scribe in training would progress to more advanced literary compositions, such as the popular story of Sinuhe; didactic (i.e., instructional) literature, which frequently extolled the virtues of the scribal profession over the indignities of manual labor; and model letters designed to teach the proper format for correspondence. Most, perhaps even all, of these types of pedagogical com-

► THE HOUSE OF LIFE

One of the most important centers of scribal activity in ancient Egypt was the House of Life (*per ankh*). It was once believed that this institution functioned as a sort of university for the training of scribes. However, a careful reading of the extant sources indicates that the House of Life was actually a sort of scriptorium where the countless religious texts (including magical and medical treatises) were edited and compiled by advanced scribes. Many such institutions existed, and they were generally located at or near major temple complexes. The scribes working at the House of Life were closely associated with the nearby cult centers, and many priests doubtless spent a portion of their time engaged in state-sponsored research into matters of religious importance at the House of Life.

—Joshua Roberson

positions could be compiled in textbooks for use at schools. One popular example of this type of compilation is the Eleventh Dynasty Book of *Kemit* (Summation), which includes epistolary greetings, a short model letter, and a stereotyped autobiographical text. Once the basic training was completed, a junior scribe would begin an apprenticeship under the tutelage of a senior official or administrator. If the junior scribe performed his duties well, he might then hope to distinguish himself as one who was *jqr djeba'u* (excellent of fingers), an esteemed man of letters and valued member of the king's bureaucracy.

The Mesopotamian E-Dub-ba

Children generally learned their parents' trade or occupation, although some were apprenticed to learn other skills, as young slaves often were. For the children of the well to do, many of whom would become scribes, there were formal schools. Schoolrooms—known as "tablet houses" (*e-dub-ba*, Akkadian *bit tuppi*)—have been uncovered in Ur, Nippur, Sippar, and the Mari palace, and Sumerian texts describe the curriculum and other aspects of schooling. School was run by a master scribe, the "school father," paid out of the students' fees and assisted by an advanced scholar known as "big brother" and sometimes by masters in particular subjects such as drawing and Sumerian. Pupils were kept hard at work, with only six days a month off, and they were beaten for various offenses, including late-

> MESOPOTAMIAN "SCHOOLDAYS"

An Old Babylonian text ("Schooldays") vividly conjures up the student's day and his sufferings: rising in haste, he urges his mother to hurry with his packed lunch—two bread rolls—but arrives late and is punished, not for the last time that day. In the evening his father listens sympathetically to his son's complaints and invites the teacher over, plying him with food, drink, and gifts, while his son strives to display his deference and desire to do well. The teacher is mollified and flattered; eventually he praises the boy's application and assures him of success. This little story was a popular text that students copied to practice their writing skills.

—Jane R. McIntosh

ness, speaking or standing up without permission, and poor-quality work.

In late-third-millennium and Old Babylonian times, there was a set curriculum pursued in schools; earlier and later the course of study varied, but the basic elements were the same. The beginner, seated on a cloth in the courtyard, was taught to form cuneiform symbols in the sand. He progressed to learning how to prepare a clay tablet and reed stylus for writing and began his studies, copying on one face of the tablet the signs that his teacher had written on the other. Schooling since the earliest days around 3000 BCE had been in Sumerian, but by the early second millennium this was a dead language that the pupil also had to learn. Many of the surviving textbooks are Akkadian-Sumerian dictionaries. The student copied lists that introduced him to the written forms of many categories of words: plants, animals, professions, places, minerals, and many others. As he became more proficient he began copying more complex texts, including literature, model letters, and law codes, acquiring a knowledge of grammar and vocabulary and of broader skills and information that would stand him in good stead in his adult career. Surveying and mathematical exercises also loomed large and were concerned with such practical matters as the rations required to feed

enough workmen to dig a canal of a given length or the time needed to build a siege ramp.

The teacher was expected to help his students obtain suitable posts in the civil or temple service. Literacy was a valuable asset, even to those not destined to work as scribes. Several kings boasted of their scholarship. Many royal and private family letters survive in archives such as those from Kanesh and Mari. They range from exchanges on purely business matters to chatty information on domestic dramas and complaints about parental neglect and filial bad behavior.

■ Introduction: Early Writing

Writing was one of the most important contributions that the people of the period from 4000 BCE to 1000 BCE made to world culture. This invention lies at the heart of much of the world's accomplishments and achievements. Writing is a means of expressing language visually (as opposed to orally or aurally). There is nothing about language itself that necessitates the development of a writing system, although it is hard for us to now imagine a world without writing.

The first writing was likely invented in Mesopotamia, even though Egyptologists and Sinologists argue that writing developed first in Egypt and China respectively. This controversy is not likely to be solved any time soon since an answer is dependent on the accidental finds of archaeology and the development of a consensus on what constitutes writing and what are better thought of as symbols.

The reasons for the invention of writing are multiple and seem to differ from society to society. In Mesopotamia, the earliest attested writing is found on accounting documents. However, literary texts dating to very soon after have also been recovered; the difference in time between the first Mesopotamian economic texts and the first Mesopotamian literary texts is not archaeologically significant, thus the claim that writing was invented for business purposes alone is de-

batable. In Egypt the first artifacts with writing (if it can be considered writing) are labels with the hieroglyphic signs for various cities. Chinese writing is first attested for purposes of divination and communication with the gods. Since no one can read the Proto-Elamite texts from Iran or the writing from the Indus Valley, it is impossible to be certain about the functions of writing in these cultures. However, given that they appear to be analogous to economic tablets and seals bearing personal names and occupations from Mesopotamia, it is likely that writing at least fulfilled an administrative role in these cultures. Linear A, found on Crete, also cannot be read, but for various reasons scholars presume that these were administrative texts as well.

—Kevin M. McGeough

Egyptian Hieroglyphs

The Egyptian hieroglyphic script remained in use for nearly 4,000 years, from the earliest known examples on ivory labels found recently at Abydos, in Middle Egypt (ca. 3500 BCE), to the latest datable hieroglyphic text from the island of Philae, far to the south (ca. 340 CE). Despite this remarkable longevity, the number of people who could actually read and write hieroglyphs at any one time was never more than a tiny percentage of the Egyptian-speaking population (probably

less than 2 percent). During the last centuries of pharaonic Egyptian history, even this small number began to dwindle, as command of the hieroglyphic script became an increasingly esoteric skill of the priesthood.

The word “hieroglyph” derives from the term used by the Greeks to describe the Egyptians’ monumental writing system, *ta hieroglyphika grammata* (holy carved letters), which must be distinguished from the cursive hieratic script used on papyrus documents for day-to-day communication. The Egyptians’ own name for the hieroglyphs, *medu netcher* (words of god), reflects a firm belief in the divine origin of writing. At the same time, the individual hieroglyphs themselves could also be viewed as entities with inherent power. This principle is illustrated by an early Old Kingdom autobiographical inscription in which the very signs used to write the text were described as *netcheru* (gods), made in stone by the tomb owner as an imperishable record of his deeds.

Given their divine nature, hieroglyphic signs also carried the potential to magically harm, especially when used in a funerary context. Because of this danger, signs representing animals such as snakes and crocodiles could, on occasion, be drawn with heads separated from bodies, pierced by knives, or cut in half with stylized grains of sand placed between the severed portions, thus magically preventing their reattachment. Even signs depicting seemingly benign creatures such as birds or human figures could be ritually mutilated in this fashion. To the Egyptian, a sign or symbol always drew a portion of its essence from the thing signified, and the pictorial character of the hieroglyphs combined with their divine status made them a particularly effective means of manipulating this power.

Through the centuries leading up to the modern era, the most common misconception regarding the hieroglyphic writing system was the mistaken assumption that hieroglyphs were used exclusively as some sort of esoteric, and largely allegorical, pictorial code. This view can be traced back at least as far as the fifth century CE to the Greeks, whose belief in the occult meaning of the characters colored western perceptions of the Egyptian language for more than a millennium. This belief only began to be seri-

ously challenged with the discovery of phonetic correspondences for certain hieroglyphic signs on the now-famous Rosetta Stone by the British polymath Thomas Young in 1814. Building upon Young’s work, the final breakthrough came in 1822 with Champollion’s irrefutable confirmation of the script’s phonetic character. After this point, modern understanding of the hieroglyphic script and the language it conveyed progressed rapidly. Egyptologists can now profess a reasonably thorough understanding of the principles underlying the writing system (orthography, syntax, etc.), which has opened the door for exploration of the finer points of grammar, cognition, and lexicography.

Most scripts developed for the purpose of recording human speech can be traced back to pictorial forms, which were simplified and schematized over time. This observation holds true for the writing systems of dead languages such as Akkadian and Sumerian as well as for scripts still in use today, such as Chinese, Hebrew, and our own borrowed Roman characters, whose origins may be traced back to the alphabet of the Phoenicians. Egyptian hieratic, the aforementioned cursive script, exhibits this same tendency. By the Ramessid era (ca. 1315–1081 BCE), many earlier sign forms had been abstracted to a system of simple strokes combined with highly stylized characters that often bore little obvious relation to their hieroglyphic counterparts. Monumental hieroglyphs, on the other hand, represent the opposite pole of this phenomenon. Rather than simplifying, the inventory of hieroglyphic signs actually increased over time. Even more importantly, the various objects and creatures represented always retained their identity and distinctive character as miniature works of art, irrespective of their value as sound-signs or ideograms.

Two basic principles underlie the use of the Egyptian hieroglyphic script (note that the word “hieroglyphic” should only be used as an adjective, as opposed to the noun “hieroglyph”). These are the use of sound-signs (phonograms) and idea-signs (ideograms). Phonograms were used to spell out the sounds, or phonemes, of the Egyptian spoken language, similar to our own alphabet. To this end, the original significance of a sign as an object, creature, etc., was dropped in

➤ ART AND WRITING IN ANCIENT EGYPT

Two of the most recognizable aspects of the culture of ancient Egypt are its highly distinctive mode of artistic representation and the monumental hieroglyphic script. The near-simultaneous development of these two features appears to have begun around the terminal protodynastic period as a tool of the newly created central bureaucracy. The formal principles that underlie the production of both two- and three-dimensional art were intimately linked with the pictorial signs used for the hieroglyphic script. The pictorial or artistic character of the hieroglyphs is well known, and many of the hieroglyphic texts rank as some of the finest examples of relief and painting known from ancient Egypt. However, the countless scenes, which illustrate tombs and temples, as well as statues of humans, kings, and gods, also possess a hieroglyphic aspect, enabling an observer to read the figures in scenes themselves. The posture and gestures exhibited by human figures almost invariably mimic the forms of hieroglyphs; thus, a man shown addressing a god may stand in the posture of the sign meaning “to call, address,”  while representations of the dead praising the sun in the underworld adopt the form of the hieroglyph meaning “to praise, adore,”  etc. In addition to the figures’ posture, the emblems held in their hands, as well as clothing, crowns, and other objects in a given scene virtually all possess hieroglyphic counterparts, lending additional depth of meaning to the tableau. In fact, the Egyptians, who possessed no known word for “art” in the modern sense of the term, appear to have understood text and image as complementary aspects of the same phenomenon. Art and writing were essentially tools for the expression of concepts and ideas in a manner that would endure longer than the spoken word, thereby creating a *menew*, or “monument” (literally “enduring thing”), to be read by future generations.

—Joshua Roberson

favor of its phonetic value, which was generally derived by means of the rebus principle (e.g., the consonant “r” was written with a mouth, which derived from the Egyptian word for “mouth,” *ro*). In addition to signs conveying a single consonant, Egyptian also possessed a number of biliteral and trilateral signs representing groups of

two or three consonants, respectively (hieroglyphic Egyptian did not typically use vowels). The various so-called alphabetic signs could then be strung together to spell out the sounds of any given word. With the exception of cryptographic texts, most phonograms in classical Egyptian possessed only one primary, consonantal value as opposed to languages such as Sumerian and Akkadian, which could assign many different sounds to a single sign.

Ideograms, unlike phonograms, derive their meaning from the object or creature represented by the sign in question. Signs used in this way can represent actual words, as in the use of a disc to write the word *ra* (sun). However, since a single glyph could have multiple ideographic readings, these types of signs were very often accompanied by less ambiguous phonetic complements, which helped to clarify the reading of the main sign. Thus, the disc used to write *ra* could also be used as an ideogram for *heru* (day). The inclusion of phonetic complements eliminated the potential for ambiguity between the two words. In addition to ideograms, which carried information about the actual sound of a word, other signs functioned as so-called determinatives, which were placed after a word to clarify its meaning but carried no phonetic value of their own. Because Egyptian did not typically use vowels, the use of determinatives became especially important when two different words shared the same group of consonants. For example, the word *mes*, meaning “child,” was spelled identically to another word *mes*, meaning “calf,” and yet another, meaning “bouquet of flowers.” By placing a picture of a seated child, a calf, or a bundle of plants after the word, these various meanings could be easily distinguished. The majority of Egyptian words were, in fact, written in this way as a combination of phonograms, ideograms, and determinatives. However, it is also important to note that the hieroglyphic system was extremely flexible with the ways in which these signs were chosen, and very few words possessed anything resembling a fixed orthography. This is particularly true with regard to the inclusion or omission of determinatives and phonetic complements.

As a direct result of the built-in flexibility of the hieroglyphic script, the Egyptians also devel-

oped an alternate system of phonetic and ideographic sign values, which have been described as cryptographic or enigmatic by modern scholars. The use of enigmatic writing in Egypt may be observed in virtually all periods, from the Old Kingdom through Greco-Roman times. These alternate sign values began to be standardized in the New Kingdom, although the Egyptians themselves never appear to have coined a term to differentiate cryptography from more standard hieroglyphic inscriptions. Cryptographic sign values were derived in a number of ways that have the potential to seriously tax the ingenuity of would-be decipherers. Signs could be drawn from unusual angles or replaced with variant forms; phonetic similarity of consonants (e.g., “d” for “t,” “b” for “p,” etc.) could be exploited; many signs could acquire abnormal phonetic values, especially through the reduction of weak or omissible elements (the so-called consonantal principle); the usual order of signs could be switched; and signs could be altered for thematic, mythological, or purely aesthetic reasons. Fortunately, a large number of cryptographic texts were accompanied by transcriptions into regular hieroglyphic Egyptian, which has enabled scholars to proceed on surer footing with other texts that lack such convenient cribs, to borrow a term from modern cryptanalysis. In any event, the most recent research suggests that most cryptography was probably not intended to hide a text’s message from the uninitiated. On the contrary, cryptography appears to have been meant to entice the reader to speculate on the nature and content of the obscure spellings and may even have served as a sort of signpost pointing to the occurrence of certain philosophically challenging portions of a longer narrative, which would eventually yield up their secrets to the persistent reader.

Linear A and B and Earlier Aegean Scripts

Bronze Age Aegean society is often described as prehistoric, that is, without written sources. This is not entirely true. Two different writing systems, called Linear A and Linear B, were in use. Linear A belongs to the palace society on the island of Crete and the cultural realm of the Minoans. Linear B is a similar script, but it was the method of writing for Mycenaean society on the Greek mainland.

In approximately 1900 BCE a palatial society arose on Crete with several large palaces at various sites, the largest at the city of Knossos (present-day Heraklion). It was here at Knossos that the Minoans developed a written script to help them deal with the increasing bureaucracy of the palace economy. The archaeologist Arthur Evans, who excavated Knossos, called the script Linear A because the signs were made up of different combinations of lines. Linear A became the standard system of writing on Crete in the Bronze Age, but it has not yet been deciphered. Since its discovery more than 100 years ago, various scholars have claimed that they have indeed deciphered Linear A. One of the better-known theories was proposed by Cyrus Gordon, who claimed that Linear A is actually a Semitic language related to Canaanite. His conclusions have not met widespread support, and as of yet there is no accepted decipherment.

Linear B uses the same signs as Linear A but represents an altogether different language. This

➤ PHAISTOS DISC

The Phaistos Disc is one of the most enigmatic artifacts to emerge from Minoan archaeology. It was discovered at the Palace of Phaistos and can be dated by its archaeological context to circa 1700 BCE. The artifact is a flat clay circular disc covered on both sides with pictographic signs arranged in a spiral. The signs were impressed on the clay using stamps or punches, just like a printed document. Vertical lines separated groups of signs and must have served as word dividers. It is not clear where to begin reading the document or in which direction. Although it is sometimes assumed that this document is a foreign object, for nothing else like it has ever been found, a few of the signs do in fact have parallels with hieroglyphic signs inscribed on an object found at the Arkalochori cave on Crete, and many resemble Linear A and B signs.

Over the years there have been many interpretations and translations of the disc. These range from some outlandish suggestions printed on the Internet to interpretations of the disc as a cultic calendar, board game, or mathematical treatise. The languages that the Phaistos Disc are said to represent also range from Slavonic to Greek and Canaanite. The most recent attempts focus on an Indo-European language called Luwian of southern Anatolia and related to Hittite or some other early Indo-European language. As with Linear A, there is no consensus on any of these interpretations or translations. Because the Phaistos Disc is a one of a kind document, there is virtually no way to check

Dating from about 1700 BCE, the Phaistos disc, an artifact found on Crete, contains an undeciphered pictographic script. (Gianni Dagli Orti/Corbis)

a decipherment through a comparison with another document. Until parallels are discovered by archaeologists, the Phaistos Disc will continue to baffle us.

—Susan Helft

is not unlike the modern world in which the Latin alphabet is used to represent languages as different as Turkish, Russian, and English. Unlike Linear A, Linear B was deciphered in 1953 and conclusively shown to represent an early form of Greek. Linear B thus proved once and for all that the Mycenaeans were indeed the progenitors of the later Greeks.

Linear A is older than Linear B, which adopted Linear A's signs, but even Linear A was not the oldest script used in the Aegean region. Even before 1900 BCE, scattered groups of pictorial signs such as hieroglyphs were used on small

objects on Crete. Although these inscriptions, like Linear A, cannot be deciphered, some of the hieroglyphic signs show a picture of some commodity, such as a sheep, and a number next to it. Like the Linear B archive, these too were economic texts.

The most famous example of a hieroglyphic inscription on Crete is an enigmatic clay disc-shaped object covered in hieroglyphic pictographs. This was found at the palace at Phaistos and is called the Phaistos Disc. The relationship between the hieroglyphic script, the script on the Phaistos Disc, and Linear A, all of which

share several signs, is not entirely clear. It used to be assumed that Linear A was a development of the earlier hieroglyphic script. Instead, they may represent different regional dialects or even different languages in use by the Minoans.

Both writing systems, Linear A and B, are syllabaries. In an alphabet each letter represents one consonant or one sound. Before the alphabet was invented, however, scripts used one sign to represent one syllable, such as *ka* or *ki*. Signs in Linear A and B represented either a single syllable or sometimes an entire word. There were also separate signs to represent numbers and fractions.

Inscriptions in Linear A and B are generally short transaction records or inventory lists. The primary purpose of the script was for economic records in the palaces. A few inscriptions are short dedications to gods, and there are also short inscriptions on sealstones or individual signs used to mark pottery or building stones. As in Mesopotamia, both the Minoans and Mycenaeans used wood or reed styli to impress their signs into small clay tablets. These tablets were not intentionally baked in order to give them permanence. Unfortunately for us, unlike the Mesopotamians neither the Minoans nor the Mycenaeans ever produced a body of literature such as mythologies, royal inscriptions, or historical works. Therefore, the corpus of Linear B texts is of limited use to the historian. What the texts do show is that Aegean society, like most ancient societies, was nearly illiterate except for the scribes. In addition, writing was closely tied to the palaces, where almost all texts are found. When the Aegean palaces were destroyed around 1200 BCE, so were the traditions of writing in the Aegean until a new tradition, the Phoenician alphabet, was introduced to Greece in the eighth century BCE.

The Alphabet

The words in this sentence are written using a technology that emerged almost 4,000 years ago in the eastern Mediterranean: the alphabet. Although a number of societies have developed writing systems, the alphabet appears to have been a unique invention that diffused from the Near East to Africa, Europe, East Asia, and the Americas in the subsequent millennia. Any writing system can be used to approximate any human language, but the first alphabet appears to have been developed around 2000–1750 BCE in the southern Levant or Egypt to write an ancient Semitic language, Proto-Canaanite, also called Proto-Sinaitic. A common ancestor to the later Hebrew and Arabic scripts, the earliest alphabet consisted of consonants only.

An alphabet is a writing system in which there is a discrete correspondence between one sound (called a phoneme) and one symbol (called a grapheme). The word “alphabet” derives from the classical Greek term for the first two letters of their alphabet, *alpha* and *beta*, much in the way the alphabet is called the ABCs in the English-speaking world today. In fact, abecedaries are texts that simply record the order of the alphabet. As in present-day schools, one basic way to learn an ancient alphabet was to practice writing it out. This repetition led to the standardization of the order of the alphabet in the latter half of the second millennium BCE, and aspects of that order have been preserved down to the present.

The earliest documented writing emerged in the ancient Near East near the end of the fourth millennium BCE. Cuneiform and hieroglyphs from Mesopotamia and Egypt were the earliest writing systems, and both dominated the written records of the region for millennia. Against this background, the first alphabet was a latecomer on the scene and was at first not very significant. Even though the early alphabet was comparatively easy to learn, literacy rates probably remained rather low.

The very first alphabetic inscriptions are still not completely understood. The Proto-Canaanite alphabet contained fewer than 30 distinct characters. It was used to write a few personal names and titles as well as some longer dedicatory

inscriptions. This earliest script is also sometimes called Proto-Sinaitic because the majority of the inscriptions were found in the Sinai Peninsula. However, this designation is probably too specific, since similar alphabetic inscriptions were recently discovered at Wadi el-Hol in Upper Egypt not far from Luxor. These earliest alphabetic inscriptions date broadly to about 2000–1750 BCE.

The first alphabet was essentially pictographic, meaning that the symbols represented real objects in the world. The current theory is that some peoples from the Levant devised these pictograms in either Egypt or the Levant. One likely source of inspiration came from the visually evocative hieroglyphs used to write Egyptian, but there is no direct link between hieroglyphic Egyptian and the first alphabet. Like the Egyptian symbol for “house,” the earliest pictographic form of the letter “B” looks like the top plan of a simple building. This pictograph is appropriate for writing “B” because the early Semitic word for “house” started with the “b” sound, *baytu*. The pictograph for “house” could thus be used to represent the “b” sound in any word. A contemporary analogy would be to draw a balloon to express the “b” sound. This principle is what modern scholars call the acrophonic principle.

After the basic shapes of the letters were established by the acrophonic principle, the forms of the letters became more linear and abstract in the latter half of the second millennium BCE. The alphabetic inscriptions from the southern Levant in this period are called linear Canaanite. Like the Proto-Canaanite inscriptions, these are mostly personal names and votive inscriptions on objects. A parallel alphabet is attested on clay tablets from the coastal city of Ugarit, Syria, in the fourteenth to thirteenth centuries BCE. The alphabet used in these texts is remarkable because it consisted of cuneiform (wedge-shaped) symbols. The inspiration for these characters was the syllabic cuneiform writing system from Mesopotamia, which was also used at Ugarit in the same period.

In most alphabetic inscriptions from the second millennium BCE there is no punctuation, no divisions or spaces between words or phrases,

and no distinction between upper and lower case. The direction of writing was fluid. By the end of the second millennium BCE, word dividers were used sporadically, and the direction of alphabetic writing (left to right at Ugarit; right to left in the southern Levant) became more or less standardized on the local level.

The Greek alphabet resulted from a dynamic cultural interaction between seafaring Phoenicians and the Greek world around 1000 BCE. Speakers of early Greek did not recognize some of the consonantal sounds present in the Phoenicians’ Semitic language. These linear Phoenician letters were thus adapted in the Greek world for approximating the vocalic quality of the Semitic consonants. The early speakers of Greek came to use these signs to write vowels.

A number of publications have photographs and drawings of early alphabetic inscriptions. The West Semitic Research Project (University of Southern California), <http://www.usc.edu/dept/LAS/wrsp/>, maintains a useful digital archive called InscriptiFact, <http://www.inscriptifact.com/>.

Harappan Writing

During the late fourth millennium graffiti on pottery at Harappa began to include some distinctive signs that in the following Early Harappan period were sometimes used in sequences of two or three signs. These were arranged in the sign order subsequently adopted in the fully fledged Harappan (Indus) script, which emerged during the Transition period (2600–2500 BCE). This was used by the Indus civilization on seals and other objects and served many purposes. However, when urban life declined in the early second millennium BCE, the script went out of use. Some of its signs appeared occasionally in later contexts, not as script but probably as auspicious religious or political symbols. Nothing links the Harappan script with the Brahmi script that appeared more than 1,000 years later.

Of the surviving objects bearing Harappan writing, the most common are the square stamp seals. Only a few sealings made using such seals are known. Small engraved copper tablets, inscribed on one face and bearing a design on the other, were found at Mohenjo-daro. These may have been amulets, as may the many miniature tablets of steatite, faience, and terra-cotta found in the upper levels at Harappa, which bear a short inscription on one face, sometimes with a design, and often a number on the other.

Small inscribed objects included bronze axes and chisels, gold jewelry, bone hairpins, ivory and bone rods, and painted terra-cotta bangles. The inscriptions may be the owner's name or a charm to ensure the object's safe use or to protect the owner. Some may record a votive offering. Inscriptions were impressed on many pots before firing, perhaps giving information on the designated contents or capacity of the vessel. Small, very fine stoneware bangles bearing a short inscription, manufactured at Mohenjo-daro

➤ ZEBU BULL—HARAPPAN SEALS

Zebu Bull seal from the city of Mohenjo-daro.
(Harappa Archaeological Research Project, Department of Archaeology and Museums, Government of Pakistan)

The Zebu bull is an exclusive motif found on the large Harappan seals excavated from big cities of the Indus Valley civilization. The bull has broad curved horns and heavy dewlap with long hair on its neck. Seals having Zebu bulls on them usually have very short inscriptions due to its well-defined form. The Zebu bull was not worshiped as a god but instead was most likely a sacrificial animal. It was the symbol of power and strength as the leader of the herd. On stone seals the bull symbolizes the most dominant clan or powerful leader.

—Muhammad Aurang Zeb Mughal

and probably Harappa under carefully regulated conditions, may have been badges of office.

A unique inscription was found at Dholavira: a line of nine huge signs made of a white crystal-line material. These had probably originally been set on a wooden board over the North Gateway to the citadel. The text probably had some religious significance, perhaps purifying or blessing those who passed under it.

The surviving inscribed objects served only some of the functions to which writing can be put, probably including marking ownership (artifacts), personal or official identification (seals), preventing tampering, managing distribution (seals and sealings), and dedications, spells, prayers, or benedictions (miniature tablets, copper tablets, inscribed artifacts). Most literate societies also used their writing to keep economic records, and it seems unlikely that the Harappans were the exception, so they probably also used other writing media that has now vanished. In more recent times many perishable media have been extensively used in the subcontinent for writing: wood, cotton cloth, bark, palm leaves, and parchment, all of which, if used by the Harappans, would long since have decayed away. Several clues suggest that the Harappans used objects similar to the wooden writing boards used by modern South Asian schoolchildren.

The script for Harappan writing is undeciphered, but detailed studies have revealed much about its nature. It uses a large number of signs. Some are unambiguously pictorial, such as the (headless) stick man; many seem abstract; and many others seem pictorial, but it is not clear what they show (e.g., a sign that resembles a jar with handles might alternatively represent a cow's head). A few signs appear very frequently, with the most common 20 signs accounting for around half the content of the inscriptions over the whole corpus. Some are known from a single example, and many others occur only a few times.

Identifying the corpus of different signs should provide important information, but this is far from straightforward. Many signs look similar to each other. Some are probably allographs (different accepted ways of writing the same sign). Others, however, must be different signs with different semantic or phonetic values. The problem is distinguishing between these possibilities. A similar problem is posed by ligatures. These are two to six signs combined in various ways: by joining them with a line, by writing one inside another or one above another, or by superimposing parts of one sign upon another. They may be a space-saving device, allowing a complete word or phrase to be written as one; alternatively, the ligatured sign may express a meaning obliquely related to the sum of its parts

or differing entirely from all of them, so it is difficult to determine whether each ligature should be considered as a separate sign. While there is no agreement on an exact figure, the number of Harappan signs lies somewhere in the range 350–700. This matches the number of signs in a logosyllabic script, generally 400–700 signs; alphabetic and syllabic scripts use far fewer signs (20–35 and 100–150, respectively).

Words are typically 1 to 3 signs long in logographic scripts. The majority of Harappan texts are very short, around 1 to 8 signs; the longest continuous text is 17 signs, few have 10 or more, and quite a few have only 1. This is partly because most texts needed to convey very little information, such as a name or dedication.

A few other features of the script have been worked out. Various pieces of evidence (such as which end of the line a space or sign crowding occurs) have satisfactorily demonstrated that the Indus script was written from right to left in rows from the top downward. Numbers in scripts can often be identified using clues from their form and behavior. Obvious candidates for the numbers in the Harappan script are sets of short and long parallel strokes, some arranged in several rows.

The complex task of deciphering a script involves identifying both the language in which it was written and the meaning or sound represented by each sign. The pictorial meaning of a few Harappan signs seems clear, and sometimes Harappan art confirms this. For example, the suggested fish sign is identical to a fish shown in a crocodile's jaws. But for many other signs it is hard or even impossible to identify their pictorial meaning. For example, a vertical stroke with horizontal lines might be a comb, a harrow, a tree, or none of these. Many scholars have taken the pictorial signs as a starting point in their attempts at decipherment. Ideally, if the underlying language were known, these could yield words clustered around their pictorial meaning and one or several homonyms.

The language of the script is, however, still unknown. It cannot have been Indo-Aryan, as linguistic evidence shows that this language entered the greater Indus region later and was influenced by the languages already spoken there. These probably included Para-Munda (a recently

identified Austro-Asiatic language), possibly Meluhhan (perhaps related to Para-Munda), and probably Proto-Dravidian (an ancestral Dravidian language). The hopes of many scholars are focused on the latter. A number of persuasive Dravidian-based sign readings seem to give consistent results, but they are too few to offer proof. A major drawback is that apart from Proto-Dravidian, very little is known of the plausible candidate languages.

Many factors hamper the decipherment of the Harappan script: the absence of bilingual inscriptions to provide a starting point, the stylized form of most signs, the very limited length and nature of the texts, ignorance of the underlying language, the failure of the script to evolve into later scripts, and the complexity of logosyllabic scripts. It is therefore likely that the Harappan script will continue to defy attempts at decipherment for the foreseeable future.

Chinese Writing

To those who do not know Chinese, the appearance of the Chinese language is altogether novel: instead of neat rows of alphabetic letters, there are thousands of unique characters, many of which seem incredibly intricate. The diversity of these characters is also fascinating, both visually and aurally. For example, the word "China" requires two characters, and there are two accepted variations. (As the illustration indicates, the second version substitutes the simplified character designated here as "d." for "b.") Can-

The word China, two variations. (LaFleur, Robert Andre. *China: A Global Studies Handbook*, 2003)

tonese Chinese pronounce this word *junggok*; people from Shanghai pronounce it *zonggoh*; and Mandarin speakers say *zhōngguó* or *chūngkuó*. Can any of these be isolated as the correct form and pronunciation for the word "China"?

In fact, no, as all of them are right. Chinese is not as "simple" as English, which has only one five-letter word representing the name of the largest country in Asia. Variety is what the Chinese language is about, and all aspects of this variety have evolved through China's long history. The respective pronunciations for the word China—*junggok* in Cantonese, *zonggoh* in Shanghaiese, and *zhōngguó* in Mandarin—represent three of the eight major dialects of China.

The legendary Cang Jie (c. 2500 BCE), the official historian of the Yellow Emperor, is often credited with the invention of the earliest Chinese characters. According to folklore, Cang Jie had an extra pair of eyes that brought him extraordinary discernment. Inspired by the natural objects around him, particularly by the footprints of birds and animals, he ostensibly created the pictographic symbols that marked the beginning of the Chinese written language.

The actual origin of such a sophisticated writing system is, of course, less simple. The early pictographs were reflections of daily life, and they developed gradually from various sources. Thus Cang Jie can be considered the collector and organizer of existing signs and symbols, rather than the genius who successfully and single-handedly created an intricate communication method. Still, the legend surrounding his contribution remains—the first computer program for building characters that were not yet in the vocabulary pool, developed in the 1980s, was named after Cang Jie.

The oldest form of the Chinese written language can be found in the oracle bone inscriptions called *jiǎgǔwén*. Carved on tortoise shells

	oracle bone inscription	bronze inscription	Small Seal script	Clerical script	Regular script
	甲骨文	金文	篆文	隶书	楷书
moon	𠄎	𠄎	月	月	月
people	𠤎	𠤎	人	人	人

mountain	山	山	山	山	山

Evolution of written Chinese. (LaFleur, Robert Andre.
China: A Global Studies Handbook, 2003)

and mammal bones during the Shang dynasty (c. 1600–1100 BCE), these inscriptions recorded royal events and documented divinations. Each symbol represented a concrete image: a number, an animal, a tree, a mountain, the sunrise, and so forth. These early inscriptions demonstrate the inconsistencies found in primitive writing: an idea can be carved with many strokes or with just a few. Likewise, character size varies, and character positioning can be upright, sideways, or reversed. The strokes of these symbols mainly take the form of straight lines with sharp ends made with forceful carving knives.

During the late Shang dynasty and throughout the Zhou dynasty (c. 1100–256 BCE), bronze inscription, *zhōngdīngwén*, prevailed. This form of inscription refined oracle bone inscription. Although its earliest characters resembled the oracle bone inscriptions, curved lines are common in bronze inscriptions. Characters in this form were more regular in size and mainly upright. The number of characters was also greater: the large text inscribed on a single piece of bronze in the Zhou dynasty could contain as many as 500 characters.

The standardization of Chinese characters began under the first emperor of the Qin dynasty (221–206 BCE), who founded the first unified Chinese empire and ordered the unification of the written language. This standardized writing, called the Small Seal script (*xiǎozhuàn*), was the official national script designed by the court of the Qin. The characters in the Small Seal script are highly stylized, with each confined

to a vertically oblong shape. The lines are even, thin, and wiry; the space is carefully regulated, and the pictorial elements of earlier writing forms are not apparent. Although the Small Seal script was crisply distinctive, its composition required patience and skill, so it was inconvenient for daily use.

The Clerical script (*lìshū*) began to appear at the end of the Qin dynasty and was adapted as the formal writing form during the Han dynasty (206 BCE–220 CE). As its name suggests, the Clerical script was initially used by clerks for the daily documentation of government records in the early Han. Reaching the height of its popularity in the Later Han period (CE 25–220), it simplified the complicated curves of the Small Seal style and replaced them with straightened lines and angles for clarity in reading and ease of writing. The Clerical script marked an important change in Chinese writing, for, hereafter, Chinese characters progressed from ancient symbols to their modern form.

Following the Clerical script was the Regular styled script (*kǎishū*), which came into use at the end of the Han dynasty (CE 220). It is an austere script that eventually replaced the Clerical for daily official functions. The Regular has been the formal script and remains the standard printing type in China today. Its major features are clarity and legibility—every character has a definite form and a square shape, and only minor variations are allowed. Each character in the Regular script clearly displays the basic strokes of Chinese writing that Chinese school children learn and practice.

■ Introduction: Cuneiform Scripts

Mesopotamian cuneiform was probably the world's first writing system, but it is essential to understand that cuneiform itself was not a language. The term "cuneiform," meaning "wedge-shaped," was first used by Europeans in the early nineteenth century CE to describe the basic character of this indigenous Mesopotamian script, which, aside from its very earliest form, consisted of various combinations of wedges. Cuneiform was written primarily by using a reed stylus to impress characters onto clay, one of the few abundant natural resources in ancient Mesopotamia. However, cuneiform signs have also been found inscribed on stone, metal, and other media. The cuneiform script is attested in use for well over three millennia, from approximately 3200 BCE to 100 CE. In that time cuneiform was adapted to render a wide variety of different languages from many of western Asia's language families. Some of the most prominent languages written in cuneiform were Semitic (related to later Hebrew and Arabic) and Indo-European (related to later Sanskrit, Spanish, and English). However, the first language written with cuneiform was Sumerian, a language isolate (meaning that it is not related to any other known languages), and it was later adapted to write Semitic Akkadian, with its northern Assyrian and southern Babylonian dialects. Semitic Eblaite and Ugaritic as well as the unrelated Hurrian language appear in northern Syrian cuneiform documents. Indo-European Hittite and the unrelated Anatolian languages Luwian, Palaic, and Hattic are found in Asia Minor. Elamite and Old Persian are native to Iran, and Canaanite dialects are found in the southern Levant. Urartian appeared later on in Armenia. Individual words in Amorite, Kassite, and Egyptian are attested, as are personal names, place names, and divine names from the region's numerous other ethnolinguistic groups, very few of which survived in writing at all. Only some of the languages spoken in the ancient Near East can be confidently identified. Although the vast majority of cuneiform documents have been found in what is today Iraq, cuneiform inscriptions are also known from present-day Syria, Turkey, Iran,

Egypt, Israel, Lebanon, Jordan, Armenia, and Saudi Arabia.

The Origins of Cuneiform

In its earliest stages the cuneiform script appears to have been almost entirely logographic, which means that individual characters expressed complete words, both concrete ("sheep," "bread," "city") and more abstract ideas (numbers). Over time, cuneiform was also adapted to express syllables that were various combinations of consonants and vowels. On the whole, this writing system stands in sharp contrast with the alphabetic systems that developed well over a millennium later. From the earliest periods until the end of the third millennium about 700–800 cuneiform signs were in use, and additional signs were used to represent numbers. In the first quarter of the second millennium, the minimum inventory of characters necessary for functional literacy was reduced to only about 70–80 signs.

The remarkably persistent use of cuneiform throughout much of the ancient world represents a paradoxical blend of tradition and innovation. In this respect, the diffusion and influence

► ENMERKAR AND THE ORIGINS OF WRITING

A number of literary narratives from the Old Babylonian period (ca. 1750 BCE) recount the deeds of legendary kings of the southern Mesopotamian city of Uruk. Among these kings are Gilgamesh, Lugalbanda, and Enmerkar, who are said to have embarked on distant campaigns and engaged in diplomatic exploits. One of these texts is a Sumerian legend referred to by modern scholars as “Enmerkar and the Lord of Aratta,” but in ancient Babylonia it was called “City, Awesome Bull,” referring to the city of Uruk itself. A passage from this tale sheds light on some ancient Mesopotamian beliefs about the invention of writing. Here, writing emerges as a practical tool to preserve a long and complicated message from King Enmerkar, referred to by the title “Lord of Kulaba,” to his rival the Lord of Aratta, an unnamed leader of a mythic far-off land outside of Mesopotamia. The message is too difficult for the messenger to memorize, so Enmerkar takes some clay in his hand and writes the first cuneiform tablet:

“His (Enmerkar’s) speech was substantial, and its contents extensive.
The messenger, whose mouth was heavy, was not able to repeat it.
Because the messenger, whose mouth was heavy, was not able to repeat it,
The Lord of Kulaba patted some clay and wrote the message as a tablet.
Formerly, the writing of words on clay was not established.
Now, under the sun and on that day, it was indeed so!
The Lord of Kulaba set the words as on a tablet, it was indeed so!

The messenger then travels to the land of Aratta, delivers the message, and instructs the Lord of Aratta to read it and give his reply in the contest:

‘Enmerkar, the son of (the sun-god) Utu, has given me clay.
O Lord of Aratta! After you have looked at the clay, after you have learned the content of the message, say whatever you will say to me,
...
I shall announce that message in the shrine Eana (temple in Uruk) as glad tidings
...
to Enmerkar, the son of Utu.’

...

After he (the messenger) had spoken thus to him (the Lord of Aratta),
the Lord of Aratta received from the messenger his kiln-fired clay.
The Lord of Aratta looked at the clay.
The words just spoken was mere nails, and his brow furrowed.”

The Lord of Aratta’s brush with the frustration of illiteracy is then interrupted by the storm-god thundering in the sky. But how could Enmerkar expect the Lord of Aratta to understand the written message since Enmerkar had himself just invented writing? The invention of writing occurs here in the context of a series of contests between the rulers of Uruk and Aratta for the rightful patronage of Inana, the Sumerian goddess of sex and war. Enmerkar’s invention of writing to attain victory in this contest represents the Mesopotamian belief in the superiority of Mesopotamia’s urban literate civilization. Nevertheless, the larger narrative also illustrates the awareness that Mesopotamia was heavily dependent on trade with the surrounding regions and cultures.

It is telling that both ancient Mesopotamian scribes and modern scholars locate the invention of writing in the southern Mesopotamian city of Uruk, biblical Uruk. Both ancient and modern observers also relate the creation of the cuneiform writing system to the administrative need to preserve large amounts of information over space and time. In Old Babylonian schools “Enmerkar and the Lord of Aratta” was probably memorized and then copied out from memory by advanced students. This adds a layer of humor to the messenger’s inability to remember Enmerkar’s message and the Lord of Aratta’s frustration and inability to read the written message.

of the cuneiform script is somewhat akin to that of the Chinese script and, for example, its later adaptation to write Japanese. Just as Old Japanese texts (ca. 700–800 CE) are written using only Chinese characters and can thus be understood in either language, there are cuneiform tablets that appear to be written in Sumerian but can also be read in Akkadian.

The textual corpus of cuneiform tablets is in general very large, although some periods and genres are much better attested than others. This is largely a by-product of chance preservation and archaeological excavation. Only a fraction of the cuneiform tablets that have been excavated have been thoroughly studied by modern scholars, and untold numbers of tablets remain unexcavated. The looting of archaeological sites for cuneiform tablets remains a serious problem in the present-day Middle East.

The first major attestation of cuneiform texts coincides with the invention of writing itself. Although the archaeological sequence in Mesopotamia goes back much further, it is only with the advent of writing that it becomes possible to put together historical and ethnolinguistic aspects of Mesopotamian society with the vast material culture from the region. Both ancient Mesopotamian literary tradition and modern archaeology place the invention of writing at the major southern Mesopotamian site of Uruk in the so-called Archaic period or Uruk period, about 3200 BCE, although modern scholars continue to argue about the precise date. The language of these earliest texts is not certain, but it was probably Sumerian, the name ascribed to it by the later inhabitants of Mesopotamia, who called the most southern region Sumer.

At this earliest phase the cuneiform script was pictographic, which means that the characters generally looked like the objects they represented, but often even the earliest signs bore no obvious resemblance to objects in the world. In later phases of cuneiform these signs are stylized to such an extent that they are no longer truly pictographic in nature. Although cuneiform signs changed significantly over time and space, this evolution typically happened at a slow rate, so it is possible to put the different forms of the same sign in a chronological and geographic sequence.

Trade dictionary containing the cuneiform script in different languages for widely used merchandise, for metals, textiles, clothes, oil, and cereals, third–second millennium BCE, Susa. (Erich Lessing/Art Resource, NY)

A very early group of cuneiform texts has also been found in Elam in southwestern Iran. These sources have yet to be fully deciphered, and our current knowledge of Proto-Elamite is therefore very poor.

The partially pictographic nature of the early cuneiform script, which is more linear and abstract in later periods, is to be contrasted, for example, with the hieroglyphic Egyptian monumental script whose use began in the south of Egypt at the same approximate time or, more likely, slightly later. In stark contrast with cuneiform, hieroglyphic Egyptian never lost its pictographic nature, although other less discernibly pictographic Egyptian scripts (hieratic and demotic) emerged alongside it in the history of ancient Egyptian.

It is very difficult to read archaic cuneiform texts, but they appear to represent a sophisticated tradition of bookkeeping. This administrative use of cuneiform writing is by far the most

common in almost every phase of its use. The Archaic period also contains a large number of examples of the lists that modern scholars call lexical lists. Lexical lists were standardized compilations of signs, words, or phrases, for example, lists of different types of plants, human occupations, cities, tools and metals, and animals. Lexical lists appear to have served a fundamental role in scribal education in every phase of cuneiform regardless of the major language(s) that were currently rendered in the script. Some of these lists were preserved by ancient scholars for more than a millennium, offering strong evidence of the highly conservative nature of some critical aspects of the cuneiform writing tradition. There is no known example of an Archaic period text with complete sentences or a connecting narrative, so there is no real grammar or narrative in this period and no literature that we can recognize as such.

The Birth of Royal Inscriptions and Sumerian Literature

Significant developments in cuneiform occurred during the so-called Early Dynastic period (2900 BCE to 2370 BCE). Early Dynastic cuneiform texts are found in a greater geographic distribution than in the previous Uruk period. Significant finds of cuneiform tablets from this period come from several major southern Mesopotamian cities, such as Ur. It is in the Early Dynastic period that the first appearance of Sumerian as a written language can be proven. In addition, in what is now Syria, cuneiform tablets from Ebla preserve the first major occurrence of written bilingualism in cuneiform. In some lexical tablets the royal scribes of Ebla translated Sumerian terms into their native Eblaite, a Semitic language closely related to early Akkadian. Numerous administrative documents from Ebla are written in Eblaite, providing insight into the regional economy of the day.

This period also marks the emergence of a major genre of Mesopotamian literary activity, the royal inscription, that occurs in some form down to the end of the cuneiform tradition. Many Early Dynastic monumental or dedicatory inscriptions are preserved, typically carved on some medium other than clay such as a stone vessel or mace head. In some instances, royal inscriptions contain a narrative of important royal deeds, for example, waging of war or undertaking major architectural projects such as the building of temples. Scholars gain the first significant textual evidence of Mesopotamian political history in this period. A series of royal inscriptions describe a long-standing border conflict between the major southern Mesopotamian city states of Umma and Lagash. The most celebrated of these inscriptions is the Stele of the Vultures commissioned by Eanatum, the ruler of the Babylonian city-state Lagash (ca. 2460–2400 BCE).

The Early Dynastic period also offers the first evidence of Sumerian literature. Within Mesopotamia proper, texts of this kind are found almost exclusively at the sites of Shuruppak and Tell Abu-Salabikh, where scribes wrote down collections of Sumerian proverbs and hymns. It is in this period that the legendary Gilgamesh of

Uruk was first mentioned in religious texts. The Early Dynastic period also marks the first use of magical incantations in Mesopotamian medicine against such dangers as unspecified illness, snake bites, scorpion attacks, and the perils of childbirth.

In the Old Akkadian period (ca. 2334–2154 BCE), much of southern Mesopotamia was consolidated under the reign of Sargon of Akkad in what is arguably the world's first attested empire. The most significant advancement in the cuneiform script in this period is its use in rendering Semitic Akkadian, which functioned as the administrative language of Sargon's empire. Although Akkadian personal names are attested in texts prior to this period, the Old Akkadian texts give the first examples of cuneiform tablets written solely in Akkadian. In subsequent periods, a rich and varied Akkadian-language textual tradition evolved in Mesopotamia, complementing the earlier Sumerian textual tradition.

In the ensuing Ur III period (2112–2004 BCE), another major empire emerged based in the southern city of Ur. From a textual standpoint, this period is best known for the survival of myriad economic tablets from the major centers of the empire. The kings of the Third Dynasty of Ur reintroduced Sumerian as the major language of the bureaucracy (an example of this is the large number of texts, all written in Sumerian, recovered from a site near Nippur known as Puzrish-Dagan, where shipments of various animals were collected as tribute to the king). The earliest known version of the famous Sumerian King List dates to the Ur III period. The Sumerian King List details a sequence of legendary and actual kings in Mesopotamia from primeval times, interrupted by a disastrous mythological flood that closely resembles biblical traditions of the flood in later literary tradition. The text then goes on to link the legendary past with a list of verifiable historical monarchs. This composition is one of the first texts that permits major insight into the ways that the peoples of ancient Mesopotamia composed their own histories. The Ur III period also marks the first instance of a royal law collection in Sumerian, authored in the time of either King Ur-Namma or his son Shulgi. This law collection antedates the famous Code of Hammurabi by a few centuries. The Ur III period

➤ ELECTRONIC RESOURCES ON CUNEIFORM

There are many good resources on cuneiform writing available on the Internet. These sites preserve photographs and drawings of the inscriptions, transliterations of cuneiform into English characters, and translations, as well as provide search tools, dictionaries, and commentaries. Some of the best Web sites are listed below.

probably marks the beginning of the end of Sumerian as a spoken language of everyday life in Mesopotamia, although Sumerian persisted as a legal, literary, and religious language for centuries, akin to the use of Latin in medieval and early modern Europe.

It is in the Isin-Larsa and Old Babylonian periods (ca. 2017–1595 BCE) that the most extensive collections of Sumerian literature and lexical texts are preserved. Many of the sources come from the remnants of Babylonian schools, known in Sumerian as the *edubba* (“tablet house”), in Nippur and Ur. In this period schooling occurred in a domestic setting.

The scribal curriculum in Old Babylonian Nippur has been reconstructed in considerable detail, revealing a carefully arranged general sequence of exercises designed to teach Sumerian sign values, vocabulary, and grammar. The most elementary school exercises betray elements of the most basic didactic methods.

Among the corpus of literary texts from this period are a diverse range of myths involving important Mesopotamian deities and the creation of the first human. There does not appear to have been one single, systematic, universally accepted creation myth in ancient Mesopotamia. A Sumerian version of the Mesopotamian flood story also dates to late in this period.

Cuneiform in the Second Millennium

From the second millennium on, scribes continued to copy Sumerian texts for educational purposes. Akkadian was the spoken language of the Old Babylonian period, and the prevailing view is that Sumerian was no longer a spoken language at this time. The first significant group of literary compositions written in Akkadian is from the early second millennium. A large corpus of Old Babylonian letters written in Akkadian is particularly significant for the study of the political history of kings such as the famous Hammurabi of Babylon. An unanticipated cache of letters and other cuneiform documents was unearthed during excavations at the site of Mari near the modern Syria-Iraq border. These significant archives of royal and private correspondence illuminate the details of politics, economy, and society in this period. The thousands of private documents excavated from second-millennium family archives shed light on aspects of social history and everyday life that are only dimly known for earlier periods.

The early second millennium witnessed a number of other significant intellectual advances.

The very beginning of this era furthered the development of a standardized numerical scheme that was in use for the next two millennia of Mesopotamian history: the sexagesimal (base 60) number system, which is the origin of the modern system of counting hours, minutes, and seconds. In addition to lexical lists and literary compositions, Old Babylonian scribes also produced the earliest known textual record of pure mathematics. Other early scientific activities include advances in Mesopotamian medicine and the development of written Mesopotamian omen science.

The textual record from northern Mesopotamia is much less extensive in the early second millennium. The most important corpus from this period is from an Old Assyrian merchant colony, Kanish (modern Kültepe), in present-day Turkey. This collection of mostly letters and economic documents centered around the dynamic caravan activity that connected Assyria and Anatolia. It is in this period that scholars find the earliest evidence of relatively widespread literacy. The Old Assyrian cuneiform writing system was simplified to such an extent that it was possible for merchants to write their own tablets instead of having to hire a scribe to write letters and contracts for them.

The fall of the First Dynasty of Babylon ushers in a significant gap in the written sources, followed by the Middle Babylonian or Kassite period (ca. 1595–1155 BCE) of the cuneiform record in the south. Large corpora of cuneiform documents, including massive caches of administrative records, are known from both Assyria and Babylonia in the latter half of the second millennium, especially at the sites of Assur and Nippur. The Middle Assyrian library from Assur is an important repository of information about scribal traditions in northern Mesopotamia. The cities of Nippur and Babylon provide evidence for the uses of cuneiform in Kassite Babylonia. Outside of Mesopotamia, various cultures adapted cuneiform writing in innovative ways. The thousands of cuneiform tablets from the royal library in the Hittite capital of Hattusha furnish an example of the adaptation of cuneiform to meet local needs. International correspondence was carried out in Akkadian (and sometimes Hittite),

local documents were written in Hittite, and various literary and religious compositions (rituals, festivals, hymns, and prayers) were copied in a wide variety of Mesopotamian and Anatolian languages. The situation in Syria was similar in this period. For instance, the coastal port of Ugarit has yielded a wealth of cuneiform documents, many that were written using a new invention of the second millennium: the alphabet. This local alphabet was rendered in a new set of cuneiform characters that were derived from Mesopotamian cuneiform, but Babylonian continued to be used in other capacities at this cosmopolitan city of the Late Bronze Age. Farther inland in Syria, the site of Emar on the Euphrates attests to local use of Akkadian to draft personal documents, such as letters and contracts, but also a large collection of Mesopotamian scholarly lore and local religious festivals.

THE ZENITH AND NADIR OF CUNEIFORM

The advent of the Neo-Assyrian empire (1180 BCE) necessitated huge royal archives of administrative, legal, and literary cuneiform tablets as well as a large body of monumental historical annals. The last king of the Neo-Assyrian empire, Ashurbanipal (668 BCE), assembled an extensive library in his South-West Palace in Nineveh. This library included selections from Mesopotamian literature written throughout Assyria and, most significantly, Babylonia, and Ashurbanipal himself boasted of being able to read the most difficult of cuneiform inscriptions. After the fall of Nineveh, the subsequent Neo-Babylonian (625–539 BCE) and Persian (538–331 BCE) periods witnessed the continued use of cuneiform for a variety of royal and private documents. The multilingual Behistun rock relief inscription of the Persian king Darius the Great (549–486 BCE) provided one of the essential keys for the decipherment of the cuneiform script in the nineteenth century CE.

Historical chronicles in Babylonian cuneiform continued to be composed in the time of Alexander the Great and in the subsequent Seleucid and Arsacid periods. One striking peculiarity of this late period is the corpus of Graeco-Babyloniaca. These clay tablets are inscribed on one side with a cuneiform Sumerian-Akkadian lexical list, hymn, or incantation and on the other with a transliteration of the same text using the alphabetic Greek script in use at that time.

Paradoxically, the zenith of cuneiform learning, the Neo-Assyrian library of Ashurbanipal in Nineveh, also showed the first hints of the long decline of cuneiform into obsolescence. In addition to evidence from cuneiform documents, images from Assyrian art suggest that the Crown simultaneously employed scribes to write cuneiform on clay tablets or wax-covered writing boards as well as scribes to write alphabetic Aramaic on parchment. Over the course of the first millennium, alphabetic Aramaic slowly replaced cuneiform Akkadian as the preferred international language of the region before it too was finally unseated by Arabic.

—Matthew T. Rutz

■ Introduction: Leisure

The role of physical activities in ancient cultures provides some insight into the lack of a distinct division between play and the work necessary for daily survival. Physical culture served a variety of social, political, religious, and military purposes in ancient civilizations such as those that existed in China, Egypt, Mesopotamia, Mesoamerica, Minoan, and Mycenae. In our attempts to understand and appraise the role that physical recreation plays in our own society, it can be instructive to examine the place of physical activities in past civilizations. Through an examination of play elements in ancient societies it becomes clear that these activities were employed for critical ends. They defined relations between people and mediated interactions, especially regarding conflict.

Physical activities that can be broadly defined as sports represent universal human experiences and are found in every culture. Defining cultural practices that are inclusive of sport may be as simple as focusing on play activities, that is, those practices that are not necessarily work and are participated in for reasons other than survival. Yet there are numerous examples of sports, games, and contests that harbor greater cultural meaning and relevance than to be defined simply as play in a pejorative sense.

Johan Huizinga defines play as activities that are free and out of the ordinary. He does not suggest that play is unimportant but argues that it is necessary or even essential to any culture. These often sacred activities serve to promote and reinforce the formation of social groups. Play, whether it is done for fun or other more practical purposes, serves society in ways that ordinary or everyday activities do not. Clearly, work activities have generally received the most attention by those who have studied past civilizations. However, it is necessary to delve into the complexities of activities outside the ordinary to recognize the important religious and cultural functions that occurred during times of rest, celebration, or religious worship.

Play, particularly in its physical forms, represented a complex activity that held an important place in all ancient civilizations. Whether the

goal was to train warriors in the martial arts, solidify the privileged position of a ruler or members of the ruling class, or provide a means to try to influence supernatural forces, play and games served vitally important functions in the ancient world. Did men and women who lived in the world's earliest civilizations recognize these activities as being less important than other aspects of their lives? It is doubtful that this would have been the case. Yet today our understanding of play, games, and sports as secondary concerns continues to impact the manner in which these activities as they existed in the past are considered.

Figurines

Figurines—sculpted artifacts depicting human beings or animals—have been produced over the past 30,000 years of human cultural history.

Throughout the ages, figurines have been crafted out of diverse materials such as mammoth ivory, bones, stone, baked clay, wood, leather, wool, cloth, straw, and other materials. As for the distribution of figurines depicting human beings in the cultures of the world, there are marked disproportions. Where both sexes are represented, the female figurines are more elaborate than the male ones (e.g., at Çatalhöyük in Anatolia). There are numerous cultures where an abundance of female figurines is common, including the Paleolithic in western Europe and in central Siberia, the Neolithic Era in the Near East, Anatolia and southeastern Europe, the Pre-Columbian cultures in Mesoamerica, and the traditional matrilineal societies in central Africa, among others.

➤ FIGURINES AS DOLLS

One of the popular interpretations of prehistoric figurines is their identification as dolls—that is, toys—for children. This idea is based primarily on the visual impression of certain types of figurines and on the association that these may evoke in the modern beholder's cultural memory. The general association with dolls is ambiguous, however, because it leaves space for various interpretations that for the most part are not related to the realm of children's toys.

In a typological-functional overview of dolls in the cultures of the world, only little variation can be observed for the category of dolls as playthings. Surprisingly, the greatest variety of doll types can be distinguished for the category of dolls not to play with. The first to study dolls as a serious scholarly subject was Max von Boehn. The dolls that are not meant for playing with are imbued with a symbolic meaning induced by cultural tradition. This is true, for instance, for the Japanese imperial dolls that feature members of the royal family. Such dolls, which are usually kept in small show-cases and placed in prominent spaces in Japanese people's homes, are objects of respect, a crystallizing element of Japanese identity.

Dolls that carry a spiritual meaning, such as the Kachina dolls among the Hopi Indians in New Mexico, play a similar role. These dolls are given to children not to play with but as instructive pieces for young people to learn about the spirit world, about different categories of spirits and divinities, and about their functional ranges. Among the traditional Kachina, there is one type with which an infant may play, although this function is not primary. The cradle doll, called Hahayiwuuti (Happy Mother), is believed to bless the child with attributes of good motherhood, making it a happy human being.

In certain cultures, doll-like figurines play a role as healing devices, as in the tradition of the worry dolls among the Maya in Central America. The worry dolls have remained in use up to the pres-

ent. According to Mayan beliefs, these dolls made of soft material attract pains and worries and relieve those who keep them under their pillow overnight.

There are also doll-like figurines that are as much imbued with cultural as spiritual meaning. This is the case with the Matrioshka dolls, which are assembled as a set of dolls within dolls. The popularity of these dolls is so widespread that they may be considered the most typical symbol of Russianness. The Matrioshka dolls are a metaphor and visualize the idea of Mother Russia, of the female guardian who protects Russian territory and those who inhabit it. The Matrioshka dolls were created by the Russian artist Sergei Maliutin toward the end of the nineteenth century and have enjoyed popularity ever since. There is an even deeper historical background to the idea of the protective mother figure that finds its origin in the cult of the pre-Christian goddess Mokosh among the eastern Slavs. Mokosh personified the Earth Goddess, and her attributes of motherhood later merged with the figure of the Virgin Mary.

The absence of written sources for prehistoric periods has spurred scholarly imagination about the possible function of figurines in the communities of hunter-gatherers and of early agrarians. Interpretations have focused on the role of female figurines in communal life in par-

ticular. These interpretations range between two extremes, one being strictly profane and the other focusing on the sacred.

In the history of the study of figurines, a strictly profane use of figurines has been emphasized by some investigators who identify them

Ceramic figurine from Ashdod (named “Ashdoda” by the excavators), twelfth century BCE. (Zev Radovan, *Land of the Bible* Picture Archive)

as children’s toys. Some scholars see the educational function of toys as one that teaches children about power relations in society. In such approaches, the projection of concepts of power relations in modern society onto the conditions of social organization of community life in prehistory seem to prevail over a genuine assessment of the symbiotic relationship between the visible (artifacts) and the invisible (symbolic meanings)—the fabric of any culture—in a prehistoric context.

Symbolic and metaphorical meanings are highlighted by others who provide insights about spiritual associations. In many cases, the context in which the figurines appear indicates a symbolic meaning of these artifacts. Often, they are associated with sacred spaces such as

shrines, ceremonial platforms, or altars. Circumstantial evidence favors the assumption of a metaphorical function of female figurines, which would fall in line with the insight that the world of prehistoric people was spirited.

Thus, a female figurine—assumed to be infused with spiritual power—shifts its identity from being a sculpture to becoming the embodiment of a divine female spirit or of a venerated ancestor. According to the mind-set of members in a community for whom a parallel world—the spirit world—exists apart from the real world, the figurine does not only depict a female human being, it *is* the venerated ancestor or a female deity.

Assumptions about metaphorical identifications of figurines are supported by certain categories of artifacts such as receptacles or vessels with anthropomorphic features. In the archaeological record of the Neolithic in Southeastern Europe, for instance, there are cult vessels for offering with the shape of a female body or with breasts and arms of a woman or clay models of shrines with a woman’s head on top. One also finds hybrid figurines with both anthropomorphic and zoomorphic features (e.g., a female figurine with a bird’s head and arms like a bird’s wings).

Valuable insights supporting a spiritual interpretation of the role of female figurines in prehistoric societies come from anthropological and ethnographic comparisons with living traditional cultures. A well-studied domain of spiritually oriented imagery is concerned with the figurines produced and venerated in the Luba community, a people living in the southeastern part of the Democratic Republic of Congo (former Zaire). The Lubas believe that the female body has a special capacity to attract spiritual energies and that protective spirits reside between a woman’s breasts. The same properties are attributed to figurines made of wood or ivory. Some figurines are worn as pendants, and they embody the spirits of revered ancestors.

Egyptian Games

Play was certainly important to the ancient Egyptians. It is a frequent motif in Egyptian tomb art. Since the Egyptians believed that the depictions on tomb walls would become reality in the tomb owner's afterlife, pleasurable activities such as play were common subjects. The games of children are especially well attested and include acrobatics and wrestling, make-believe games, and chasing games. Games with toys (such as balls or board games) were also fun for the Egyptians. Athletic games in Egypt were tied to conceptions of male masculinity and included activities such as hunting and fighting, while other games were demonstrations of rank and status within Egyptian society.

Games of physical exercise were popular both as participatory activities and as spectacles. Numerous tomb scenes depict acrobatic contortions by individuals and with groups, creating demonstrations that at a surface level appear much like those of modern cheerleaders. Similarly, climbing scenes are often associated with the cult of the god Min, and climbing seems to have been a public demonstration sport. Children also seemed to have amused themselves with less formal variations on these, creating obstacles for each other to leap over or balance upon. Dancing was very popular as an entertainment; professional dancing girls and women performed at feasts and religious occasions.

Numerous sports demonstrated the masculinity and the virility of the player. Hunting (for sport as opposed to for food) tested the skills and status of the male hunter. Big-game hunting

➤ SENET

The game Senet, whose name means "to pass" or "to go by," was popular throughout Egyptian history. The game was played on a rectangular board divided into 30 squares (3 by 10). The winner of the two-person game was the player who managed to remove all of his or her seven pieces from the board first. The movements were determined based on throwing flat two-sided sticks that performed essentially the same role as modern dice. A player could block the other player's pieces from moving or could leap over the other player's pieces. Beyond this, the specific rules of the game are a mystery to modern scholars. Senet was associated with Egyptian conceptions of the afterlife and was often included in Egyptian tombs along with other funerary equipment. The removal of the player's pieces from the boards symbolized the resurrection of the player after death. The game is featured in some copies of the Egyptian Book of the Dead, in which the relationship between this game and funerary culture is made most apparent.

—Kevin M. McGeough

and marsh hunting were the most common types. In the New Kingdom, the pharaoh was frequently depicted as a hunter, a depiction that communicated messages about his strength as well as the fertility he brought to the land through his divine presence.

Other types of games involved contests of sorts. Perhaps the best attested in Egypt is wrestling, which is depicted in tomb art and in statuary. Other games similar to tag, tug-of-war, and arm-wrestling were also played by the Egyptians. Stick fighting was a type of mock battle engaged in by Egyptian males of all ages. This leisure activity is still played by Egyptian men today. Played in the evenings, it is now more like an improvisational dance than a physical battle. Target archery and chariot demonstrations were likewise games that originated as enactments of and practice for combat.

The Egyptians also played games with toys. Balls have been recovered archaeologically, and it is doubtless that there were many variations

of games played with these balls. Those that we know of include juggling and throwing according to complex rhythms or while seated on a crawling individual. One particular game is depicted on the walls of the Temple at Luxor. There, the pharaoh is shown hitting a ball with a stick toward priests who try to catch the batted ball.

Board games were popular past-times for adults. Of most interest is Senet, the equipment for which has been found at Egyptian sites. Other board games include: *men* (endurance), a game where players race tokens along a board; *mehen* (serpent), a game that was played on a board, shaped like a coiled-snake, with numerous accessory pieces; and Twenty Squares, which some have suggested is the earliest form of the game Parcheesi, well known from India and still played in the United States today.

The Sporting Life in Mesopotamia

Beginning in the middle of the fourth millennium BCE, successive empires ruled the Mesopotamian region. Societies within these cultures were engaged in almost continuous war, which in part explains their high regard for physical strength. This strength arose not only from the body but also from the variety of weapons and tools that could improve physical power. There is some difficulty in locating reliable information about the physical culture of these early Near Eastern civilizations. Evidence from sites in ancient Mesopotamia is scattered and often difficult to interpret. This problem is evident in Sumerian seals that depict wrestlers. It is not known whether these were athletic contests or

actual mortal combat. Despite this concern over interpreting evidence, displays of physical ability represented important cultural practices.

Myths and epic narrations that celebrated heroic deeds such as those of Gilgamesh, the king of Uruk, suggest that extraordinary strength and physical prowess were required of a hero or warrior king. For the warrior, the most important weapons were the bow and arrow, the dagger, and the sword. In addition, the ancient war wagon, which allowed warriors to move quickly, was first used in ancient Mesopotamia at the end of the fourth millennium BCE. The mastery of weapons while driving a war wagon required special training that was limited to aristocratic and royal youths. Often these military skills were honed during the hunt.

A ruler's feats of hunting wild and dangerous animals such as lions, wolves, boars, and panthers represented both the social function of protecting their subjects and a means to demonstrate their physical abilities. The close connection between hunting and war is evident in the god Ninurta, who represented both of these activities. Stele pictures of lion hunting date to the earliest Sumerian period, and artwork depicting rulers hunting is evident throughout the successive Ancient Mesopotamian empires. A carved stone monument referred to as the Lion Hunt Stele from the late Uruk period (3100 BCE) depicts a man in a net skirt hunting lions. Hunting dangerous animals such as lions represents a common signifier of high political office or royalty in ancient Mesopotamia. During the period of Assyrian dominance, the hunt became a spectacle whereby animals were enclosed and controlled for the ruler to demonstrate his prowess before his assembled subjects.

Demonstrations of physical ability also played a role in determining some legal proceedings. Cuneiform archives from the town of Mari provide accounts of river ordeals in letters sent to the king of the Mari, Zimri-Lim (1775–1760 BCE). River ordeals took place in the town of Hit on the banks of the Euphrates, where custom suggests that people traveled to the site to seek divine justice. The ritual ordeal began with a statement of the details related to the cause of the dispute. The test involved the performance

of a physical feat in the river and ultimately emerging alive. An individual or team would be required to swim a specified distance into the river and return. Normally the swimmer would carry a heavy object while completing the test. Although it might be difficult to suggest that this ordeal was sport rather than a legal remedy, it is clear that the physical abilities of the participants were being tested during this ritual.

Festivals, which were part of the cycle of renewal, included merry-making, pleasure and leisure pursuits such as music, dancing, drinking, and sex. As part of the festivities there were reenactments of myths such as the fight between Gilgamesh and Enkidu along with animal fights and martial contests between men. Scenes depicted on limestone panels and cylinder seals from the late fourth and early third millennia depict men fighting. A document of Hittite origin from 1200 BCE describes sporting events associated with festivals that included staged fights between groups of men and a running race for the right to hold the reins of the king's chariot. It is not clear, however, whether these activities were actual contests or mythical demonstrations.

In ancient Mesopotamia the body was not viewed as an object of great interest and was not depicted in art or viewed as an artistic entity. This can be explained in part by the lack of interest in individual attainment in deference to the interests of royalty and the gods. As such, sporting events were never seen as very important in and of themselves, but they did exist in the culture of these ancient civilizations as a means to reinforce the power and privilege of the kings and gods.

➤ GILGAMESH AND THE HEROIC TRADITION

The *Epic of Gilgamesh* is an example of an ancient masterpiece in which the ordeals and feats of the warrior king are detailed to examine the frailty of existence and mortality that is the human condition. Although the author of this story is unknown, it is clear that the setting of Uruk and the person of Gilgamesh were real. Reliable sources document that Gilgamesh was the sovereign of the city of Uruk in 2600 BCE who was lauded for constructing great defensive walls around the city. Sometime after his death, Gilgamesh was elevated to a divine legend. Stories related to the feats of Gilgamesh included his defeat of Huwawa, the protector of the Pine Forest, along with his compatriot Enkidu; the slaying of the Celestial Bull by the two heroes; and finally Gilgamesh's descent into the underworld to retrieve precious talismans. Several versions of the epic are found in the archaeological record, but the most complete was found in the ruins of the library at Nineveh. The Akkadian story focuses on Gilgamesh's broad and powerful physique and emphasizes that the most-favored man is the most worthy to achieve immortality but is doomed to fail to reach such a lofty goal.

Greek Sport—Minoa and Mycenae

Two ancient civilizations that preceded the ancient Greek culture of the first millennium BCE were the Minoans based on the island of Crete and the Mycenaeans who populated the southern

➤ HOMERIC GAMES

The earliest written account of sport and athletic activities in the western world can be found in the *Iliad* and the *Odyssey*. These epic poems are generally attributed to the Greek poet Homer from about the eighth century BCE. The events described are supposed to be based on the earlier Mycenaean civilization circa 1200 BCE. These stories describe a violent age of a male-dominated and class-structured society where religion centered on the gods of mythology including Zeus, Apollo, Hera, Poseidon, and Aphrodite, all of whom existed in human likeness and influenced mortals' lives while ruling the world from Mount Olympus.

According to several passages from these accounts, competitive physical activity existed for one main purpose: to train upper-class men to become worthy warriors. Yet within this training the Greeks were also competitive, and the participants sought victory to honor the gods and demonstrate their prowess as warriors. This is particularly evident in Book 23 of the *Iliad*, which provides a detailed description of the funeral games held in honor of Patroclus, a friend and comrade in arms of Achilles, at the time of the Mycenaean siege of Troy. A variety of contests took place during this ceremony, including a chariot race, boxing match, wrestling match, foot race, and javelin throw, for which the winners received prizes ranging from jars of olive oil to horses and slaves. This story exhibited both the importance of athletic ability to the worth of ancient Greeks and how physical contests, like life, were fraught with danger and depended heavily on luck and the favor of the gods.

—Robert Kossuth

regions of Greece in the latter centuries of the second millennium BCE. Both of these cultures seem to have had some influence on later ancient Greek civilization, although both disappeared well before 1000 BCE. Archaeological evidence suggests that the Minoans and the Mycenaeans participated in ritual-based physical activities, although little is known about the social meanings of these practices.

The discoveries made at the Tomb of Agamemnon and the Palace of Minos at Knossos on

Taureodor (bull leaping) fresco from the Minoan palace of Knossos, about 1500 BCE. (Wolfgang Kaehler/Corbis)

Crete provide evidence about the life and the physical activities of these ancient Greek civilizations. Yet much less is known about their nature and cultural significance. The bull-leaping fresco at the palace at Knossos dates from about 1500 BCE and depicts the acrobatics of two white female figures and a red male figure. The first female is shown grappling the bull's horns in preparation to perform a front somersault onto the animal's back, while the second female stands at the rear of the animal in preparation to assist a male acrobat who is preparing to hand-spring off the bull's back. It is possible that these figures represent performers providing entertainment for the royal court. A further explanation is that the youths were engaged in a fertility ordeal or ritual. Ritual bull leaping was likely an activity that incorporated both physical contest and religious ceremony in a manner similar to later Greek athletic contests.

Reliefs found on the gold Vapheio Cup from Aghia Triada (Boxer Vase) depict boxers, wrestlers, and what seem to be Minoan hunters. As with the bull-leaping images, all that can be taken from these representations is that these activities took place in Minoan society. Thus, it is difficult to accurately argue the larger social meaning of these activities beyond the supposition that they were valued physical practices.

As limited as our understanding of the place of physical activity in Minoan society is, even less is understood about these practices in the lives of the Mycenaeans. What is known is derived from archaeological evidence, particularly

that associated with funeral rituals. A recently discovered coffin from Tanagra depicts bull leapers, sword fighters, and charioteers, all part of a procession of mourning. A second example of a funeral ritual is found on the larnax from tomb 22, where some bull games are depicted. Three men are shown jumping on bulls and clinging to the horns. On the other side of the sarcophagus, two fighting men are depicted. It is not known whether the game and the fight are part of the funeral ritual in honor of the deceased or whether the depictions memorialized the achievements of the deceased. One theory is that these were rites of passage where the progression from childhood to adolescence was marked by a test: the youth probably had to pass a physical test, such as hunting or bull games. Finally, the container depicts horse-drawn chariots being used in a funeral procession. It is suggested that these images represent either Mycenaean funeral rites or a mythical/legendary event, or both. It is also suggested that fighting contests held at funerals for deceased leaders may have been used to select a new leader.

The Minoan and Mycenaean civilizations demonstrate a fragile link to the later ancient Greek athletic practices. Although their forms of physical culture were similar, the sacred importance for each seems to have differed; whereas the Minoans celebrated the emergence of life and fertility, the Mycenaeans employed physical contests as part of the ceremonies associated with death.

Music and Dancing in Ancient Egypt

The importance of music and dancing in ancient Egyptian culture is evident from the numerous depictions of dancers and musicians in ancient

Egyptian art as well as the large number of musical instruments scattered in museums around the world. Music and dancing served both secular as well as ritual functions in ancient Egypt. Banquet scenes are commonly represented on the walls of ancient Egyptian tombs, especially those dating to the New Kingdom (1550–1069 BCE). Scenes of dancers frequently show them accompanied by people clapping their hands, using clappers, or playing drums, sistra, tambourines, *menat*-necklaces (an emblem of the goddess Hathor, patroness of music, song, and dancing, that consisted of a beaded necklace with a counterpoise that produced a rattling sound when shaken), or any other type of percussion instrument that would keep rhythm. Examples of scenes showing dancers accompanied by flutists do exist. It is, however, unclear whether dancers were also accompanied by a whole orchestra, since representations of dancers and musicians are usually shown on the same wall, but on different registers, and even when represented on the same register, they were clearly separated.

Music and dancing played an important role from the earliest times in ancient Egyptian history. Even in the Predynastic period (5500–3100 BCE), pottery vessels showed representations of female figures that appear to be dancing with their arms raised above their heads, and musicians were represented on Predynastic artifacts such as stone vessels and ceremonial palettes.

Dancing

It is important to point out that there was no ancient Egyptian word for "dance" that covered all aspects of the concept but rather more precise words referring to specific types of dance or movement. Dances were usually, but not always, performed by women, most often by very young girls. Some dances, however, were performed by men. Group dances were segregated, for there are no scenes showing men and women dancing in the same group. Some of the movements represented on tomb walls are closer to acrobatics, including such movements as cartwheels and backbends. Religious dance in ancient Egypt falls into the following categories: (a) dances of the gods, for instance, the son of Hathor, Ihy, is

known as the divine dancer; (b) cult dances in honor of the gods, usually performed in temples; (c) dances performed during festivals; and (d) dances accompanying funerary rites. The final group comprises the oldest dances known from ancient Egypt, the most famous of which were performed by what are known as *muw*-dancers. These dancers are attested from the Old Kingdom (2686–2181 BCE) until about the end of the New Kingdom (1550–1069 BCE). They are identified by their headdresses, which were made of papyrus stalks. They were represented dancing at tomb entrances, and their role was to symbolically ferry the deceased to the netherworld.

Music

There were four main types of musical instruments in ancient Egypt: idiophones, membranophones, aerophones, and cordophones. The idiophones included such instruments as cymbals, bells, clappers, and sistra and were particularly popular during religious events. For instance, sistra were associated with the worship of the goddess Hathor, the patroness of dance, music, and song. The membranophones consisted of tambourines and drums. The former were often played by young girls at banquets, while the latter were played in religious processions and military events. Aerophones included flutes, what may be identified as double clarinets and double oboes, as well as trumpets. Finally, the chordophones included the indigenous harp as well as the Asiatic lute and lyre, which were all plucked rather than bowed. Instruments were often inscribed with the owner's name and decorated with images of the gods Hathor and Bes (a domestic deity and patron of childbirth, humor, drunkenness, song, and dance).

There seems to have been a hierarchy of musicians in ancient Egypt. Temple musicians occupied the highest level, followed by musicians of the royal household. Entertainers who played music at banquets occupied a lower position to those of the first two categories. Music was also practiced for pure pleasure, for there seems to be evidence that workmen kept themselves motivated and entertained while they worked by singing.

In short, the ancient Egyptians, very much like ourselves, used music and dance to add life to their celebrations, but for them these two activities carried much more meaning. They were sacred and played a very important role in their religious lives.

Ancient Chinese Sport

Although there is little evidence to suggest that the ancient Chinese participated in sport and athletics as we understand them from a Western perspective, there are terms that point to the existence of a developed sphere of physical culture. These descriptors include words representing martial valor (*wuyong*), boxing valor (*quanyong*), games (*xi*), the art of attacking (*jiji*), and the art of keeping fit (*yangsheng*). Ancient Chinese physical culture included a variety of activities associated with military training, rituals, medical treatment, and art and was strongly influenced by economic, political, cultural, and philosophical ideas.

Since the Xia dynasty, which existed from approximately 2100 to 1600 BCE, China has been ruled by more than a dozen imperial dynasties. Evidence from the Zhou period (1122–256 BCE) suggests that soldiers engaged in running, jumping, throwing, wrestling, archery, sword fighting, chariot driving, and weight lifting as part of their military training. For example, *jiaoli* was originally a term for weight lifting in training for the military but later came to describe acrobatic

exercise and, more recently, wrestling. Ancient forms of wrestling were from the very earliest dynasties one of the most popular military training forms. Another example of training can be traced to the western Zhou dynasty, during which servants or soldiers would run in front of their lord, who was on horseback. Later, distance-running contests required soldiers to traverse distances as long as 93.2 miles (150 kilometers) or, when in full battle dress, 31 miles (50 kilometers) in half a day. The kicking game of *tsu-chu* is first mentioned authentically in the third century BCE, although it likely had an earlier origin. This ancient game appeared in a number of variations, one being the kicking of a ball over a net similar to volleyball. Others required the kicking of a ball into or through a hole. The origin of these games is found in military training; later they became recreational activities. During the Han dynasty the football game involved two teams, each of which guarded six goals.

Physical exercise used to promote health and longevity was commonly practiced in ancient China. For example, *qigong*, a system of breathing exercises, was practiced as early as the eighth century BCE. A second form of medical exercise from this same period was Daoying. This form of exercise developed from a variety of primitive dances and consisted of movements imitating a bear climbing a tree and a bird stretching its wings. These exercises are depicted in silk paintings found in a Han dynasty tomb. There were additional exercises that imitated other animals including tigers, deer, and apes.

Chinese aristocrats tended to avoid sports in favor of achieving spiritual harmony. For example, Confucians viewed playing ball games as a sign of weak character and a moral shortcoming. Archery, however, was seen as gentlemanly and was employed as a ceremonial activity to reinforce social status. Archery games were considered a harmonious activity. *Lishe*, the ceremonial shooting of arrows, originated in the western Zhou dynasty around 1000 BCE. An aristocratic pastime, *lishe* required the use of various types of bows, arrows, and targets along with the accompaniment of music and attendants. The etiquette surrounding the event was deemed more important than the actual competition and represented

a ritual demonstration of feudal ethics rather than a competitive sport. Similarly, *Touhu*, a game that evolved from archery, involved throwing darts into a pot or kettle from varying distances and using varying sizes of targets and throwing techniques. This game of throwing into a pot was usually played at banquets by feudal lords. Archery and other throwing contests were relatively short-lived as popular aristocratic leisure activities.

Mesoamerican Ball Courts—Fusing Game and Religion

One of the most extensively practiced religious-sporting events in ancient American cultures was a ritualistic ballgame played on ceremonial courts. The religious function of these practices was to influence nature and the cosmos. Forms of these ballgames existed as far south as El Salvador and as far north as Arizona. Normally, ball courts were located near or attached to temples and often represented the sky where divine beings played among the stars. Although the actual meaning of the individual games differed, the rubber ball generally represented either the moon or sun, and the players sought to control the movement of these heavenly bodies considered so vital and important to sustaining life.

The site of the earliest ball courts in Mesoamerica, according to the available archaeological evidence, was believed to be at the Olmec site of La Venta dating from about 1200 BCE. However, new evidence of a ball court from the Mazatan village of Paso de la Amada moves that date back to somewhere between 1650 and 1500 BCE. Similarly, a tomb from El Opeño in western

➤ PASO DE LA AMADA—THE FIRST BALL COURT IN MESOAMERICA

Among the Mokaya of Mazatan the emergence of a tiered society with larger central villages and peripheral settlements began to appear between 1650 and 1500 BCE. In Paso de la Amada, one of the main villages of the Mazatan, there is evidence of the earliest examples of civic buildings that included a palace and ball court. This is believed to be the earliest formal ball court in Mesoamerica. It is argued that among this and later Mesoamerican cultures the ball game played an important role in community life by mediating relations between communities. In Paso de la Amada, the game is believed to have been contested between two individuals or teams moving a rubber ball around the court. Most formal ball courts measure between 65 and 492 feet (20 and 150 meters) long. The court at Paso de la Amada, at 262 feet (80 meters) long by 22 feet (7 meters) wide fits clearly among these and, like other early courts, was enclosed by sloping earth walls.

—Robert Kossuth

Mexico dating from about 1500 BCE contained figurines of ball players with miniature pieces of equipment. However, the earliest evidence of a ball court in that region dates to only 600 BCE. This suggests that in some instances the early incarnations of the game were played not in a court but more likely on an open field. Generally, play took place on a long court where participants attempted to knock the ball to their opponent's end using only their elbows, knees, and hips. It is believed that the presence of a vertically placed ring (often compared to a basketball hoop) was a relatively recent appearance, likely no more than 1,200 years ago. It was from these earliest civilizations that later Mesoamerican societies adopted the religious ball court game.

The mythological origins of the game are revealed through myths of the Mayan civilization. The story revolves around twin brothers who so enjoyed ball and dice games that they were lured to the place of the dead, where they lost a ball game and were sacrificed so that the lords of

Wall of the Great Ball Court at Chichén Itzá in present-day Mexico, twelfth century. At the top is the stone goal ring. (Brian Snelson)

death would no longer be disturbed by their play. The boys' severed heads were placed in a barren tree that miraculously bore fruit in the likeness of the twins. A maiden daughter of one of the lords of death took pity and visited the tree, where she was impregnated and bore twin sons who later became the sun and the moon. It was these brothers who defeated the lords of the underworld through their skill in the ritual ballgame. Thus, the ballgame represented the victory of the sun and the moon over the forces of death. There are alternate variations of this story in which, for example, the sun and the moon are resurrected from the original set of twins and the woman who gives birth to the second set of twins is a goddess.

Variations of the ballgame mythology included the moon, representing the forces of evil and darkness, to be overcome by the sun, repre-

senting life and light. The sacrifice of players in later incarnations of the game, such as that played by the Mayans, represented the rebirth of life, with the sacrifice of the moon in favor of the sun. Therefore, the display of severed heads on poles represented a rebirth in a manner similar to the myth of the brothers' heads when placed in the barren tree. The ballgame, as it was practiced, manifested religious themes and images in the ritual of its play. The game established a ritual identity for the players, priests, and fans in which man, always seeking to control nature, created a device in the ballgame to con-

front and exert control over chaotic and powerful natural forces.

■ Introduction: Architecture and Urban Planning

Architectural achievements are arguably the most famous contributions to world history in the period between 4000 and 1000 BCE. From the Pyramids of Giza to the palaces of Knossos and Mycenae to Stonehenge in England, the monuments of this age are truly inspirational feats of engineering and planning. Yet it is not just the monuments that are amazing. The cities themselves are remarkable, even though most were lost until nineteenth- and early-twentieth-century archaeologists revealed them again. Cities like Troy, Ur, and Mohenjodaro reflect extremely sophisticated urban spaces that were built and lost thousands of years ago. While cities were first built before this time, it is clear that by 4000 BCE people had begun to recognize the importance of urban space. The realization of this is reflected in the diversity of ancient urban layouts.

It is very important to understand how ancients viewed their surroundings. Urban space defines how people think about themselves and their world and how they live most of their lives. Often these values remain completely unquestioned by urban dwellers, yet they form the core of daily experience. Understanding ancient urban space is critical to understanding the daily life of the ancient world.

For archaeologists who study town plans, an important question is always whether a town

➤ THE LANGUAGE OF THE ARCHAEOLOGY OF URBAN PLANNING

Archaeologists use very specific terminology when they are discussing ancient architecture and city planning. Public buildings are those buildings that reflect state power and/or infrastructure; this is shared space that may belong to the people as a community (like a town hall) or to the ruler of a city (like a palace). Even if a public structure is used only by governing officials, it was likely paid for out of state wealth. Monumental architecture is similar. It is usually commemorative in some manner, although sometimes the term "monumental" is used simply to indicate that the structure is large. "Production zones," "industrial zones," "craft quarters," and "workshops" are all terms used by archaeologists to refer to areas where materials were manufactured. When these terms are used, they are not meant in the same sense that they are used to describe modern society, so we must not draw too many connections with modern industrial and production practices. Elite architecture is very high-end architecture, the types of houses that the very wealthy would have lived in. "Domestic architecture" can encompass elite architecture, but the term is used primarily to refer to the houses and apartments of poorer people within a city.

—Kevin M. McGeough

was purposefully planned or not. In the absence of ancient maps (although these are occasionally found, such as the map of ancient Ur), archaeologists must determine which aspects of a town were planned beforehand and which parts developed organically within the confines of that original plan. As a rule of thumb, if a layout appears to be too regular to be accidental or lines up too neatly with a preexisting cosmological perspective, then some amount of planning must have been employed. Different zones of activity that are identifiable within a city may be planned, but often these develop on their own over time.

—Kevin M. McGeough

Temple, Pyramids, and Palaces

Pyramids, temples, palaces, and state-built towns dot the Egyptian landscape and should all be considered monumental architecture. These types of structures represent a major commitment of wealth, natural resources, and labor by the state in order to venerate the king, the gods, and the power of the Egyptian state.

Although the Giza pyramids are the most famous of Egypt's pyramids, there are almost 100 pyramids known from within Egypt marking the burial places of their associated kings. In the Third Dynasty, King Djoser built the first pyra-

mid. Known as the step pyramid because of its stepped sides, it marked a major innovation in monumental architecture. Djoser's pyramid complex is built of stone, whereas previous kings built monuments using mud brick. The Fourth Dynasty king Sneferu built the first true, or straight-sided, pyramid. He managed to build three pyramids in his lifetime: a step pyramid, the bent pyramid whose slope decreases about halfway to the top due to structural problems, and the true pyramid. From Djoser to the beginning of the Eighteenth Dynasty, more than a thousand years, almost every king built a pyramid to celebrate his reign and burial. During the Old Kingdom, pyramids were built completely of layers of stone blocks and cased in finely polished white limestone that reflected the sun. By the Middle Kingdom, the core of many pyramids was built of mud brick and cased in polished limestone. These mud brick pyramids were structurally much weaker than the stone ones, and once the casing stones were removed (there is no pyramid that has retained its casing stones), they partially or completely collapsed.

In the New Kingdom, kings were buried in the Valley of the Kings. The valley is marked by a pyramidal-shaped peak at the top of its cliffs, meaning that the kings buried there are actually buried under a natural pyramid. It must be noted, however, that by the New Kingdom there was less emphasis on aspects of the solar in Egyptian religion that had been so important in the Old and Middle Kingdoms and of which the pyramid was an integral part. The move to the Valley of the Kings was also an effort to protect the royal burials from theft. The pyramid, by its very nature, is a giant marker of the wealth contained within, which almost guaranteed robbery of the burial. Kings came up with ever increasingly complicated security measures (portcullis, hidden chambers, deep pits in hallways, etc.), but none worked. In the New Kingdom, private citizens started using small pyramids over their tombs. This marked the democratization of a previously solely royal architectural form.

The pyramid has several mythological meanings. The first comes from the Pyramid Texts, a series of texts about the king's journey to the afterlife, that were written on the walls of the burial chambers in Fifth and Sixth Dynasty pyra-

Step pyramid, designed for King Djoser of the Third Dynasty by his architect Imhotep, is located in Saqqara, the main necropolis of Memphis. The structure, considered the first great monument built of stone, was started as a mastaba and enlarged twice to its current six-step shape. (Corel)

► THE PYRAMIDS AT GIZA

The pyramids at Giza are perhaps the most recognizable monuments from ancient Egypt. There are three main pyramids on the Giza plateau built by three kings of the Fourth Dynasty. An enclosure wall surrounds each pyramid. Each pyramid is also accompanied by subsidiary pyramids (also known as queens' pyramids) and a pyramid temple on the western side of the pyramid (which was attached by a causeway to a valley temple that was very near a harbor).

The pyramid of King Khufu is also known as the great pyramid because it is by far the largest pyramid ever built, about 492 feet (almost 150 meters) in height. Inside Khufu's pyramid are a series of ascending and descending passages that lead to three chambers. The king's chamber is the highest room and held the sarcophagus of the king. The middle chamber is called the queen's chamber but was probably designed to hold the king's statue. The subterranean chamber is the lowest of all the chambers and is carved out of the bedrock upon which the pyramid sits. On the western side of the pyramid are three small queens' pyramids. One is that of Queen Hetepheres, King Khufu's mother, whose burial contained a sedan chair, a bed, and a canopy, all with gold fittings. At least seven boats have been discovered buried around the pyramid of Khufu. One boat has been fully restored and reconstructed. The Egyptians believed that the spirits of the dead traveled through the underworld on boats, and the boat burials were for the king's underworld transport.

King Khafre, a younger son of King Khufu (his brother Djedefre ruled before him and built a pyramid at Abu Roash), built his pyramid just to the southeast of the great pyramid. His pyramid is almost 10 feet (3 meters) shorter than that of his father, Khufu, but because he built on a rise in the bedrock, Khafre's pyramid appears taller. Khafre is perhaps most famous for building the sphinx, which is located next to his valley temple about 1640 feet (500 meters) west of the pyramid. The sphinx is almost 64 feet (20 meters) tall at the head and about 187 feet (57 meters) long. It was carved out of solid bedrock, but the quality of the rock was poor enough to need several restorations, the earliest in the Eighteenth Dynasty.

The pyramid of King Menkaure lies to the southeast of the pyramid of Khafre and is the smallest of the king's pyramids at Giza, measuring only about 217 feet (66 meters) tall and only one-tenth of the mass of Khufu's pyramid. The reason for the downsizing of the pyramid may be linked to the growing importance of the solar cult at the time and the greater emphasis on temples rather than on tombs. To the south of Menkaure's pyramid are three queens' pyramids, two of which were unfinished. Excavation of Menkaure's valley temple revealed a series of beautifully carved statues of the king shown with the goddess Hathor, nome goddesses (the goddess of that particular Egyptian administrative region), and one of his queens.

—Vanessa Smith

mids. In the Pyramid Texts, the sun's beams shine down on Earth and act as a ramp for the king to climb to the sky in order to join his father Re, the sun. The sides of the pyramid mimic the rays of the sun coming down on Earth, and their situation directly over the king's burial ensures his pathway to the heavens. The second connotation of the pyramid is that of the primordial mound. In one ancient Egyptian myth about creation, a mound (the god Geb) rises out of the watery void (the god Nun), and it is upon this land that everything, including other gods, were created.

In the Old Kingdom, much of the focus of monumental architecture was on the burial place

of the king or his pyramid and its complex of temples. Throughout pharaonic history, mortuary temples—or those temples venerating the deceased king—remained an important part of the Egyptian monumental architectural repertoire. However, not all temples were dedicated to dead kings; many celebrated gods. In the Fifth Dynasty, sun temples were a variant of the pyramid complex, celebrating the sun god Re. At the heart of the sun temple was the benben, a rather stubby obelisk that mirrored the pyramid. Sun temples also had causeways, valley temples, and boat burials like pyramid complexes. Clearly, sun temples were meant to venerate the connection

between the living king and Re, whereas pyramid complexes honored the dead king. From the Old Kingdom only a few other gods' temples are known, and these are from provincial cult centers (such as at Medamud and Hierakonpolis).

The Middle Kingdom saw an increase in construction of temples all over Egypt, which coincided with a decrease in quality of pyramid construction. Middle Kingdom kings no longer devoted most of their assets to building mortuary monuments but instead used state wealth in a variety of religious projects. The temple Amun at Karnak, the temples of Montu at Tod and at Medamud, and the temple of Osiris at Abydos all had extensive construction during the Middle Kingdom. Unfortunately for Egyptologists, most of the Middle Kingdom temples were destroyed in the New Kingdom to allow for their remodeling and enlargement.

The New Kingdom witnessed a boom in construction of gods' temples. Not only were old ones remodeled, but new ones were built. Simultaneously, emphasis on the king's funerary monuments further decreased. The kings dug tombs into the cliffs of the Valley of the Kings and retained a permanent workforce of a few in comparison to pyramid projects. In addition, the kings built only one temple, a valley temple, instead of the two associated with the pyramid complexes. The temples of Amun at Karnak, Osiris at Abydos, Aten at Amarna, Hathor at Dendera, and Mut, Montu, Maat, Thoth, and Ptah at Luxor are some of the major divine temples that were renewed or founded in the New Kingdom.

The palace appears often in art and texts from ancient Egypt, and it is from these sources that we understand that the palace played a central role in the running of the state. Palaces acted as both the house of the king and the seat of government. The word "pharaoh" comes directly from the ancient Egyptian word for palace, *pr-aa* or "great house." Unfortunately, relatively few palaces have survived the ravages of time from ancient Egypt, mostly due to the fact that they were usually built out of mud brick. Ancient mud brick is susceptible not only to the elements but also to modern farmers who use crumbled mud brick to fertilize their fields and have destroyed many ancient Egyptian buildings. From excavations of New Kingdom palaces such

as that of Amenhotep III at Malkata or Akhenaten at Amarna, it is clear that the walls, floors, and ceilings of palaces were covered in beautiful paintings. The motifs in these paintings were of nature (birds flying over a marsh, cows running through a field, etc.) or of kingship (bound foreign prisoners, scenes of the royal family relaxing, etc.). Although not as rigid in architectural style as pyramid or temple complexes, all palaces had a few elements in common. There were large-scale columned halls and throne rooms, courtyards with pools, ceremonial areas, gardens, and a window of appearances. The window of appearances was a place where the king stood to receive visitors, to dispense rewards to courtiers, or to conduct ceremonies. The living quarters of the king are very modest given the large size of the palace as a whole. They generally consisted of a series of small rooms with bedrooms and antechambers.

Egyptian Town Planning

A study of ancient Egyptian settlements can illustrate how Egyptians planned, constructed, inhabited, and eventually abandoned their villages, towns, and cities. In a very broad sense, Egyptians usually built their towns near the Nile River and its branches, which supplied the farmers with water and fertile soil and the travelers with an effective transportation highway. The center of a town was typically the temple (and the palace in the case of a royal town), and houses and workshops of socially diverse populations developed around it. Many Early Dynastic towns (e.g., El-Kab, Edfu, Elephantine) were surrounded by

fortification walls, but in the subsequent periods enclosures were generally restricted to those of individual temples and palaces within the city, perhaps due to the relatively stable politics within the country. The cemeteries almost always developed outside the town in the nearby desert.

At a closer look, however, Egyptian towns were very diverse in appearance due to varied natural, economic, and political factors that had to be considered in choosing the towns' locations and designing their internal plans. The diversity of ancient Egyptian towns also had much to do with the history of individual towns. Especially marked differences existed between settlements that, on the one hand, originated naturally and developed gradually and, on the other, settlements that were planned and constructed as state-funded projects. The two kinds of towns might correspond to the ancient Egyptian words *niwt* and *dmi*.

The origins of gradually developed towns were often influenced strongly by geological and topographical factors. While towns were ideally located near the Nile, they also had to be situated above the river's annual inundation level so that the mud-brick buildings were not washed away by the flood. Therefore, many towns in the Nile River valley and delta developed on seasonal islands (e.g., Tell el-Daba, Memphis, Hierakonpolis), while others evolved in a linear fashion along the border between the cultivation field and the adjacent desert (e.g., Abydos, Dendera, el-Kab). Some New Kingdom royal cities (e.g., Amarna, Deir el-Ballas, Malqata) may be considered imitations of the latter type. These naturally originated towns usually looked less orderly inside because new buildings were planned and constructed at different times and by different people.

Political and economic factors played more important roles in the special towns that were founded under state supervision. For example, pyramid towns (e.g., Giza, Kahun) and other settlements associated with royal mortuary cults (e.g., Dahshur, South Abydos, Medinet Habu) were built near the related royal monuments. Similarly, villages of royal tomb builders (e.g., Giza, East Amarna, Deir el-Medina) and of royal miners (e.g., Qasr es-Sagha) were situated not too far from the respective workplaces. Furthermore,

THE SITE OF AMARNA

PLAN OF AMARNA, CIRCA 1350 BCE

Amarna (ancient Akhet-Aten) was the capital of Egypt during the reign of Akhenaten, who marked its boundary with a series of large stelae. Located on the east bank of the Nile, the city can be divided into three zones along an avenue. The central zone included several temples of Aten and the main administrative palace. In the north end of the city were the residential palaces of the royal family. Most houses and workshops were located in the southern zone. Private individuals were buried in the low desert, while royal tombs were cut into the rock farther in the wadi.

—Kei Yamamoto

STATE BUILT TOWNS

Compared to temples, pyramids, and tombs, very little is known about domestic architecture from ancient Egypt. This is because most settlements were located in the floodplain and over the millennia have been covered in layer after layer of Nile silt or are located under modern towns and cities and are inaccessible to archaeologists. Some settlements from ancient Egypt have survived and are currently undergoing intensive study. These settlements tend to be located at the edge of the desert and have missed destruction by the Nile or by modern building. Interestingly, most of these towns were planned and built by the state rather than forming organically from farming villages.

Due to the nature of their construction (with entire towns conceived and built by the state all in one go rather than organically growing over years like most villages), these state-built towns can be considered monumental in nature. From the Old Kingdom, the Giza Workmen's Village was where the workers who built the pyramids lived. The town included not only houses for the workers but also bakeries and slaughterhouses to feed them and administrative buildings for their overseers. From the Middle Kingdom the towns of Lahun and of South Abydos were associated with the burials of

King Senwosret II and King Senwosret III, respectively. The towns were founded not only to house the workers building these tombs but also to house the priests and the many other people it took to service their mortuary temples after their deaths. From the New Kingdom, King Akhenaten founded the town of Amarna to house the workmen building temples and palaces for his new capital, which was devoted to the worship of the god Aten. Deir el-Medina was a town built in the New Kingdom in Thebes to house the workmen who dug and built the kings' tombs in the Valley of the Kings.

frontier towns (e.g., forts in Nubia and North Sinai) were placed strategically, based on specific military demands and topographical features that allowed effective defense. Aided by the cubit system (1 cubit = approximately 52.4 cm), these premeditated towns often manifest orthogonal designs and repeated patterns inside, partly to maximize the efficiency in the building process and partly to impose the officials' bureaucratic policies onto its inhabitants.

Over time, the accumulation of debris turned ancient towns into tells. On the other hand, some settlements were swept away by the shifting course of the river or were buried deep under the accumulating silt, while others have been covered up completely by modern settlements. The rising level of underground water presents yet another obstacle to archaeologists trying to investigate ancient settlements in the Nile River valley and delta. Despite these challenges, the ur-

banism in ancient Egypt is much better understood today than it was four decades ago.

Egyptian Domestic Architecture

There is ongoing debate as to whether known remains of settlements accurately reflect how the majority of the population lived in ancient Egypt.

➤ FROM HOWARD CARTER TO MARK LEHNER—ARCHAEOLOGY'S CHANGING INTERESTS

The motivations that steer Egyptian archaeology have changed through time. The origin of modern Egyptology is usually credited to Napoleon Bonaparte's exploits in Egypt during the late eighteenth century. More specifically, it is attributed to the efforts of the scientists, architects, botanists, and scholars who accompanied Napoleon to study aspects of contemporary Egypt and its history, which culminated in the ambitious documentary work *Description de l'Égypte*. Two primary goals characterized the objectives of expeditions to Egypt during much of the nineteenth century: to procure exotic artifacts for Western museums and wealthy art collectors and, in some cases, to find archaeological remains that would document events and locales chronicled in the Bible. Some individuals were also spurred by the intrigue of a seemingly mysterious civilization with a strange pictographic language, the comprehension of which had been lost to the world long before.

Following Jean François Champollion's announcement of breakthroughs in deciphering the hieroglyphic language in the early 1820s, a desire for more inscriptions fueled efforts to find additional monuments. Egyptology truly arrived on a worldwide stage with the discovery of the largely intact royal tomb of King Tutankhamen (Eighteenth Dynasty) by Howard Carter in 1922. This discovery was a realization of the shift in the objectives of Egyptology research, which had already begun to focus on monumental architecture, especially large tombs and temples. A fascination with mummification (also often regarded as the territory of museums and collectors) further promoted the excavation of many cemetery sites.

Amid this backdrop, systematic academic archaeology was born under William M. Flinders Petrie in the late nineteenth and early twentieth centuries. The discipline advanced considerably through the 1960s when a coordinated international effort was mobilized for the emergency excavation, documentation, and, where possible, rescue of many Nubian sites that were threatened with imminent submersion behind the new Aswan Dam. At around this time, trends in archaeological study were already beginning to shift toward nonfunerary topics. Regional issues such as settlement patterns and urbanism became quite prominent in Egyptology from the 1970s to the 1990s, bringing houses, households, and communities into focus as important subjects of archaeological study.

Egyptological archaeologists now view houses in ancient Egypt's cities, towns, and villages as important keys to understanding ancient Egyptian society. Settlements—and even individual households—are viewed as microcosms of the broader cultural system in which they were situated. Since 1988, Mark Lehner has been applying this manner of research at Giza to address the age-old question of who built the pyramids. Under investigation is an expansive settlement comprised of eastern and western town sectors, large administrative buildings, workers' housing, production areas, and storage facilities. Ongoing excavation and analysis promises to help clarify how this sector of society was organized in its efforts to construct and maintain the funerary monuments and institutions of the powerful kings of the Fourth Dynasty.

—Nicholas S. Picardo

The basic notion of “house” was little more than one- and two-room structures represented schematically by the hieroglyphs  (h) and  (per), but in reality much more complex designs are known, including expansive structures akin to mansions. It is not advisable to speak in terms of a typical ancient Egyptian house but rather to consider houses well represented in the most preserved settlements. Archaeological remains of houses usually preserve their basic ground plans and an incomplete selection of fixtures, portable items, and trash left behind when occu-

pation ended. For long-lived houses the foundations of multiple phases of construction are often superimposed upon one another, making the task of tracing the building's history difficult.

Many of the earliest remains of houses date to the Pre-Dynastic period (prior to 3100 BCE). Some are loose collections of round or ovular huts, possibly with domed roofs. Waddle and daub and thatch construction predominated, and many houses appeared to be occupied only temporarily. This period also saw the transition to more permanent rectangular buildings arranged

in larger villages. The size of a house ranged from approximately 21 to 376 square feet (2 to 35 square meters). In many cases plastered floors were slightly recessed below the natural ground surface.

In all later periods, mud brick was the primary building material for domestic architecture, often with an exterior coat of whitewashed plaster that could be refreshed periodically as it wore away from exposure to the elements. Roofing included wattle and daub and beam-supported ceilings as well as vaulted ceilings of mud brick. Elite houses sometimes incorporated substantial components of stone and wood such as door fixtures, windows, and support columns for higher ceilings. Though three-story houses are sometimes reconstructed for illustration purposes, most if not all of Egypt's largest houses were probably one or two stories tall.

The Middle Kingdom (ca. 1938–1630 BCE) town of Kahun (also called el-Lahun/Illahun) was a state-planned, highly structured gridlike town with distinct blocks of houses of similar types. Approximately ten large mansions (about 26,909 square feet, or 2,500 square meters) occupied the most affluent sector. These buildings consisted of a residential core comprised of a three-room living area that led back to a number of private rooms behind it. In the front, a large courtyard accommodated semipublic business, the keeping of animals, and other activities. Surrounding blocks of rooms included storage chambers, granaries, cooking rooms, secondary living quarters, and other functional spaces totaling over 70 rooms and corridors in the largest houses. Small and medium houses (about 430 to 2,152 square feet, or 40 to 200 square meters) consisted of three to seven rooms and lacked the dramatic features of the large courtyard and abundant private space of the larger structures. In many buildings, stairways allowed roof access, where additional cooking and baking were undertaken in the open air.

The capital city of Akhetaten (modern Tell el-Amarna) is the most well-preserved example of an ancient Egyptian city, complete with a downtown area and suburbs. Though the city contained a high proportion of royal buildings and architecture devoted to religious rites and public ceremony, there were also sectors popu-

lated by large estates with gardens, water wells, animal pens, and dome-shaped storage silos. The typical Amarna villa house averaged roughly 2,152 to 4,305 square feet (200 to 400 square meters) and consisted of 15 to 25 rooms. It centered on a square living hall fronted by a roofed entry or reception hall and small ancillary rooms. The main hall often included a small raised platform for the owner to formally receive guests. Smaller living and sleeping rooms flanked the central hall, with private rooms such as a primary bedroom and bathroom to the extreme rear of the house. Many had at least a second floor and some usable roof space. The city's smaller houses, ranging from 430 to 1,614 square feet (40 to 150 square meters), were based on a simpler plan but also incorporated the placement of private quarters at the rear of the structure.

In the New Kingdom (ca. 1539–1075 BCE) the skilled workers (and their families) who built and decorated the Valley of the Kings were provided with villages of their own in western Thebes. Constructed of rubble-stone walls, not always joined at perfect right angles, lines of long and narrow houses were abutted against each other on the opposite sides of a main village street with their entryways facing across one another. They averaged around 53 feet (5 meters) wide by 150 to 269 feet (14 to 25 meters) long and were often not built level with the street. In a typical house, a front chamber often contained a raised bedlike fixture or shrine that was likely used for domestic ritual practices or events relating to childbirth. The next room contained a bench alongside other fixtures of domestic cults, including an inset for a bust of an ancestor or the like. One or two rooms followed that provided multifunctional space and sleeping quarters. A kitchen area occupied the rear of the house. Ascending stairways led to roof space on many houses, while descending stairways gave access to small underground storage chambers.

Nubian Cities—Areika and Kerma

Experts' knowledge of the villages of ancient Nubia is fairly limited, as only a few settlement sites have been excavated. Most of our understanding of the region comes from the excavation of cemetery sites. However, two sites—Areika in Lower Nubia and Kerma in Upper Nubia—provide good evidence for the nature of urban life in Bronze Age Africa.

Areika was inhabited by the so-called Nubian C-Group people. It was a relatively small village of about .7 acres (0.28 hectares), probably an average village size for the C-Group culture. When the site was first excavated, Leonard Woolley and David Randall-MacIver assumed that it was a fortified dwelling or castle. Further analysis, however, has shown that it was actually a small fortified community with two primary sections. On the west were the residential complexes. The houses were rectilinear in shape. This is unusual for C-Group homes, which are typically curvilinear. The eastern half of the town was a food production area. Most noteworthy is the large rectangular building, outfitted with bread ovens and 24 large storage jars. In Egypt, structures such as this were used for baking bread and brewing beer. Doubtless this was the function of the building at Areika as well. Large courtyards in the eastern section functioned as cattle pens, and a large granary provided storage space for cereal crops.

Kerma was a substantially larger city and probably a major center (if not the capital) of the Kingdom of Kush. More than 61.8 acres (25 hectares) in size, Kerma is most noteworthy for its cemetery with large tumulus tombs and hundreds of sacrificial victims. The city was defended by a wall about 11 yards (10 meters) tall that surrounded the central section of the city. Within the central section, the 200 or so households were laid out irregularly but followed a series of paths that linked the interior of the city to the four main entrances. The houses varied considerably in size and layout, but all were con-

Ancient Nubian city of Kerma in present-day Sudan.
 (Lassi Hu)

structed of mud brick. In the center of the town was a large mud-brick temple that on quick inspection appears similar to Egyptian-style temples but on closer examination deviates substantially from Egyptian architectural practices. Associated with the temple was a palace, an audience hall, and various smaller structures.

Palaces and Megarons in Greece

The Greek term *megaron* means "great hall" and is the word that Homer uses in the *Iliad* and *Odyssey* to describe the palaces of the Achaean kings. Today the term refers to a particular architectural form that lay at the heart of monumental Greek buildings in the Bronze Age. The megaron is a long and narrow hall approached through an open porch on one of its shorter sides. Megaron constructions were characteristic of the grand palaces of the Mycenaean kings

of the fourteenth to thirteenth centuries BCE, but in fact this building style was first used in Greece at the end of the Neolithic period, and megaron buildings can also be found all over the eastern Mediterranean in the Bronze Age from the Balkans to Turkey.

Monumental architecture and the construction of large central buildings that may have served as a type of early palace, or the home of a ruler, began in Greece at the end of the Neolithic period. A good example is an early form of the megaron at Dimini, a site located in the plains of Thessaly. At around 3700–3300 BCE there existed at Dimini a small, walled settlement with a megaron and courtyard set atop the hill. The large size of this building with its large open courtyard and its position at the top of the hill suggests the beginnings of social and class ranking in Greece.

In the following period, the Early Bronze Age (ca. 3000 BCE), there is a proliferation of larger,

more regular and more complex constructions that are interpreted as evidence for the growth of a wealthy ruling class in Greece at the time. These generally take the form of either a corridor house (a rectangular house with long corridors along its sides) or the megaron. An example of the corridor house can be seen at Lerna in the Peloponnese, where a large building called the House of the Tiles clearly dominated the town around 2900–2400 BCE. The material found in the House of the Tiles came from various parts of the Aegean and demonstrated that the owners of this house had the wealth and access to foreign goods to obtain valuable and exotic materials.

What we may justifiably call a palace in the more modern sense of a large and complex building that served as the home for the administrator of a city or a state does not occur in Greece until the Mycenaeans gained power toward the end of the Late Bronze Age (ca. 1300 BCE). The Mycenaean palace was essentially an

➤ MYCENAE

Mycenae holds a special place in Greek scholarship. This was the city of Agamemnon, leader of the Achaean army against Troy, mythical and tragic Homeric hero. Even today the remains of the site attest to the physical greatness of the city of Agamemnon. The city is surrounded by massive walls whose stones were so large that its construction is called Cyclopean, implying that it was carried out by the Cyclopes, the one-eyed monsters of superhuman strength.

Much of the city visible today was built at the end of the Late Bronze Age, approximately the thirteenth century BCE. But here also are the earliest indications of the growing power of the Mycenaeans. Enclosed within the city walls was an ancient burial mound called Grave Circle A where the royal family of Mycenae was buried along with gold masks and other riches. The burials remind us of Homer's epithet for the city, "Mycenae, rich in gold."

The city we see today is really only a fortified citadel, a small, walled area enclosing the palace, storerooms and workshops, shrines, and some houses of palace administrators. The houses of the ordinary townspeople lay outside the Cyclopean walls. At the top of the citadel stood the palace, a sprawling megaron building of substantial size adorned with frescoes. Little today survives of the palace besides the outlines of the central megaron.

Mycenae also boasts some of the best examples of Mycenaean architecture. One example is the Lion Gate, a large stone portal of post and lintel construction that served as the main entrance to the city. A massive stone block with a carving of two lions standing beside an upright pillar filled the triangular space above the gate and foreshadowed the importance of the triangular pediment in Classical Greek architecture. The image of lions and pillar occur often on Minoan and Mycenaean seals and seem to have been important symbols in the realm of religion and cult. Today the heads of the lions no longer exist, yet

Ruins of the Lion Gate, the main entrance to the citadel of the ancient Greek city of Mycenae. (Andreas Trepte)

the size of the pediment itself and the careful carving of the lions' haunches do not fail to impress the visitor.

Other examples of the skill of Mycenaean engineering are the lavish stone-built *tholos*, or beehive tombs, that dot the hillside around Mycenae. The excavators who found these tombs named them after the Greek heroes of Mycenae, Atreus, Agamemnon, and Clytemnestra, choosing to imagine these spots as the resting place of the great Homeric kings, although this is of course pure fantasy. These tombs were carved out of the hill and faced with stone. They consist of a large stone-built circular chamber with an open passageway leading to it. The entire structure was covered in a dirt mound so that the chamber was actually underground. Unfortunately, when these tombs were excavated it was found that they had been robbed long ago.

Today the impressive remains at the ancient site of Mycenae are a testament to the wealth and strength of the Mycenaean world.

—Susan Helft

outgrowth of the Middle Helladic megaron house consisting of a narrow room, vestibule, and porch with a fixed hearth at its center. In the palace these were of course built on a monumental scale, but this emphasizes that the palace was essentially the house of the ruler.

Over the last 100 years archaeologists have uncovered megaron palaces at Sparta, Tiryns, Athens, Mycenae, and Orchomenos. These all date to the heyday of the Mycenaean period (fourteenth to thirteenth centuries BCE). The best-preserved example comes from Sandy Pylos,

the seat of king Nestor in the Homeric tales. The palace at Pylos was entered through two small columned porches into an open courtyard. To the left of the gate were the palace archives where the transactions of the palace could be recorded. From the courtyard one enters into the great megaron, the public space of the palace. By this time the megaron form was quite standardized so that the depth of the porch was approximately half the size of the hall.

The main hall had at its center a large decorated circular hearth surrounded by four columns that held up a clerestory ceiling. Along the long wall was a stone chair or throne. On the palace walls were scenes of procession and banqueting as well as combat and hunting. In the megaron, or throne room, however, was a heraldic scene of griffins very much like the scene in the throne room at the Minoan center of Knossos. Even the floor of the main hall was decorated. It was painted to imitate a tiled floor.

The megaron hall was the heart of the palace and clearly served as the seat of the ruler. There is also some indication that the great hearth and throne were areas of ritual activity. Channels running from the throne and ashes of animals found on the hearth may be evidence for sacrifice and libations. We should therefore also consider that the Mycenaean palace was a religious as well as political center.

To either side of the megaron and generally divided by a long corridor were small rooms, perhaps used as either storerooms, pantries, or kitchens. Two rooms in particular had large amounts of drinking cups, possibly an indication of large drinking parties and feasts held at the palace. The main sleeping quarters may have been on the second story of the palace; however, second stories rarely survive in the archaeological record. At Pylos there were large storerooms with sunken pithoi probably for the storage of oils, and one area of the palace may have been a perfume factory. One can also find smaller megaron suites in Mycenaean palaces, sometimes called the queen's megaron. These areas were either more reception rooms or private apartments. The suites often included luxurious bathrooms with a large enclosed bathtub and paintings. Sophisticated drainage systems carried water and waste out of the palace.

The plans of the palaces at Tiryns and Mycenae were more elaborate but share certain general features with the palace of Pylos, such as the open court in front of the megaron and a series of galleries beside the megaron. Like Minoan palaces on Crete, many of the Mycenaean palaces have remarkably similar plans and construction techniques. This suggests that there existed a class of architects and builders that were shared among the ruling elite.

As far as we can reconstruct from the remains of the Mycenaean palaces as well as the Linear B documents, the palace was not only the home of the ruler, called in Mycenaean Greek the *wanax*, but was also the economic center of the kingdom. The palaces employed large numbers of craftsmen and slaves primarily in the keeping of flocks and the production of textiles but also for the production of luxury items including perfume, as in Pylos. The palace household represented the primary producers and consumers of elite goods. In addition to housing the royal family and being a place for state functions, we must also imagine the palace as the scene of religious rituals and large banquet feasts.

By 1200 BCE all of the palaces on Greece and Crete had been at least partly destroyed or abandoned. The world of royalty and power and the institutions of a palatial society and economy ended with their demise. The megaron form, however, survived and continued to be used in monumental buildings well into the Iron Age at places such as the Anatolian kingdom of Phrygia. The legacy of the megaron in Greece can still be seen in the layout of the Classical Greek temple for which it was most likely the forerunner.

The Palace of Minos at Knossos

In Greek mythology, King Minos was thought to have ruled the Aegean from his palace at Knossos on the island of Crete. As part of his palace, so the stories suggest, he had the mythical architect Daedalus build him a special labyrinth to house the bull-like monster called the Minotaur. In 1900 the British archaeologist Arthur Evans began to unearth the secrets of Minos's palace. Evans called the civilization that he uncovered (and what he thought was the earliest in Europe) Minoan after this legendary king.

The actual occupation of Knossos goes well back into the Neolithic period (ca. 7000 BCE) where small finds from below the palace show that Knossos was occupied even then. The city grew tremendously around 1900 BCE when a significant building, the First Palace, was built at the site. This palace lasted nearly 200 years until it was largely destroyed by a massive earthquake. At around 1700 BCE the palace was remodeled after severe earthquake damage, and this is called the Second Palace. The building was renovated again at least twice in the Late Bronze Age, the last phase of the palace remodeled by Mycenaeans from Greece. The palace that we see today at the site is mostly from this last phase, although parts of it are earlier. We should keep in mind, however, that the term "palace" is applied to this building because of its monumentality. In fact, there is no proof that this was the home or center for a single king or royal family, and we do not fully understand how these buildings were used.

The palace was built on a hilltop next to a river and covers an expanse of nearly 3 acres (21,000 square meters). It had nearly 1,000 rooms, the intricate layout of which may have given rise

to the stories of the Knossos labyrinth. The palace was likely the economic, political, and spiritual center of the town. Many scholars see a dual function for the palace as a seat of royal authority and a central shrine, perhaps reflected in the roles of the ruler himself, who would have served as a priest-king. Certain features, such as orienting corners to coincide with compass points, show that the palace was consciously planned with sensitivity to its landscape.

The approach to the palace is from a large courtyard to the west from which paved paths lead to a corridor to the south. This is called the Corridor of the Procession, as sections of wall paintings of a courtly procession lined the walls. From here one was led through a series of columned antechambers and up a staircase to the central part of the palace, the Piano Nobile, a columned audience hall just above the Throne Room and what is called the Tripartite Shrine. This area faced the Central Court, a large paved space at the center of the palace that was no doubt used for banquets, festivals, and perhaps even the famous bull-leaping games. The court tied together the two sides of the palace. The western side of the palace at Knossos, as in other palaces, was the nexus of the ceremonial and official areas and had large storage facilities. The eastern part of the palace comprised the industrial and perhaps domestic wing of the palace. On the eastern side the Royal Apartments were reached by a magnificent staircase rising three stories. These so-called apartments were suites of rooms consisting of a portico, a megaron hall, and luxurious bathrooms. In one room there was even a toilet connected to the drainage system of the palace. In the area north of the queen's megaron there is some evidence for craft workshops and storage facilities where huge storage jars lay in rows.

The palace shows very fine engineering skills. It was equipped with an aqueduct and an advanced drainage system. Its staircases were sophisticated accomplishments, and much of the palace was built of finely cut stones fitted together without mortar. The palace itself was a work of art. Many of its walls were decorated with painted frescoes, the best of which now lie in the Heraklion Museum. These showed scenes of palace life or compositions from nature. The

➤ AN ARCHAEOLOGIST'S PLAYGROUND—ARTHUR EVANS AND KNOSSOS

Sir Arthur Evans was the son of a wealthy British antiquarian with an interest in anthropology and antiquities. This interest led him to Crete, for he had seen interesting carved seal stone from there. After a few years of negotiations, Evans was able to purchase the site of the palace at Knossos and began his excavations there. He realized right away the importance of his finds. Here was a very ancient site, earlier even than Schliemann's discoveries at Mycenae, very large and very rich. Evans began to imagine Knossos as the origin of European civilization.

Over the next 30 years Evans devoted himself to the exploration and restoration of the palace. He was also a romantic and an imaginative excavator. In his notes and reports he conjures up images of the kings and queens of the palace and names the rooms according to then-current Victorian ideas about palace life. Thus, you will find on the palace plan spaces called Ariadne's Bath, the Piano Nobile, and the Grand Staircase. Evans's approach to the site's restoration has always been controversial. He practiced what he called reconstituting the palace. In many cases this meant rebuilding whole rooms, floors, pillars, and frescoes in concrete the way he imagined they must have looked. He did this for two reasons. One was a general need to conserve what was left of the original structure, and the other was to help visualize the palace's original appearance.

View of a reconstructed portion of the palace complex at Knossos on Crete, excavated and partially rebuilt by British archaeologist Arthur Evans at the turn of the twentieth century. (Paul Cowan/iStockPhoto)

Current research has shown that Evans's reconstitutions are in many cases quite fanciful. This is particularly true of his restoration of frescoes, which sometimes deviate substantially from the excavated fragments. The palace seen today at Knossos is largely Evans's creation. His partial restorations intentionally created a romanticized ruin to appeal to a modern visitor, but by doing so he gave us a static and somewhat misleading picture of the Minoan palace.

Troy

Troy was a legendary city supposedly built by the gods Apollo and Poseidon. The city of Troy gained fame through the epic poetry of the seventh-century bard Homer. In Homer's legend, Troy was the background to the daring deeds of the Greek and Trojan heroes in a ten-year siege called the Trojan War. The Trojan War has been assumed to be a factual event in history, and since the late nineteenth century Troy has become associated with Hisarlik in Anatolia in northwestern Turkey. This site has become connected to

the myth of Troy, and some excavators claim that it is the remains of the Homeric city that gives strength to the reality of the Trojan War.

In the Homeric myth, Paris, Prince of Troy, eloped with a Spartan queen, Helen, and took her back to Troy. According to Homer, the Achaeans, Danaans, and Argives were from nation-states such as Mycenae, Thebes, Pylos, and Athens in what is now called Greece and came together in some type of alliance. They were so outraged by Helen's abduction that they sent 1,000 ships, under the command of Agamemnon, king of Mycenae, to retrieve her. They besieged the city of Troy in a ten-year-long siege, but the city would not yield. Homer describes the city as being a "well built city" with "fine walls." In the *Iliad*, the walls of Troy were built by the god Poseidon who boasted of the strength of the walls to the other gods: "I walled the city massively in well-cut stone, to make the place impregnable." The walls were sacred, so it was impossible to breach them. It was only through the trick of a large wooden horse (given to the city but containing armed Greek soldiers) that the Greeks could enter the city and end the siege.

Believing that the legend of Troy was based on a historic event led German archaeologist Heinrich Schliemann to search for the city in the nineteenth century. The exact location had long been lost. In the ancient world it was believed that Troy was under the Roman town called New Ilium; however, its location could only be guessed at, but from Homer's description of Troy, Schliemann chose a hill called Hisarlik and in the 1870s began to excavate this hill.

Schliemann excavated Hisarlik in two separate campaigns (1871-1873 and 1878-1879). Although he uncovered a small settlement and fabulous gold finds, the settlement was too small and was later found to be 1,000 years too early to be Homer's Troy. After Schliemann's death, architect and assistant to Schliemann Wilhelm Dörpfeld undertook a further campaign in 1893-1894 that was paid for by Schliemann's widow Sophie Schliemann. Dörpfeld excavated cyclopean walls and fortifications that resembled the descriptions of Homer. After a break of 40 years the next excavation was by the American Carl Blegen, who uncovered a city that consisted of grand houses that he considered to have been

destroyed by earthquake and another city above it that consisted of small tenements built inside the grand houses and constructed from the rubble of the previous city. It was this latter city that Blegen considered to be Homer's Troy.

In the 1980s excavation recommenced under the direction of Manfred Korfmann, who applied new technology to areas of Hisarlik that had not been excavated for 50 years. A magnetic imaging survey of the fields revealed a ditch that contained remains and possible evidence of a battle believed to be dated to the early twelfth century BCE. The excavation of the site continues today under the direction of Ernst Pernicka.

What these excavators have uncovered is a cross-section of human existence. There were nine main cities built one on top of the other. The top city, Troy IX, was the Roman city of New Ilium founded in the reign of Emperor Augustus. This city was visited by Emperor Constantine in the fourth century, but by this time it was in decline; it eventually disappeared, and its location was forgotten. Underneath the Roman city was a Greek city, Troy XIII, visited by Alexander the Great and the Persian emperor Xerxes. This city was founded in circa 700 BCE.

The archaeological level known as Troy VII is divided into four distinct periods. These divisions are known as VIIb3 (destroyed ca. 950 BCE), VIIb2 (destroyed by fire ca. 1020 BCE), VIIb1 (destroyed by fire ca. 1120 BCE), and Troy VIIa (1300-1190 BCE). The archaeological level that corresponds to the hypothesized date of the Trojan War, circa 1240 BCE, is VIIa, and this is the most likely to be the city of Homer's Troy. With its shanty tenements, it is consistent with the image of a city at siege. Mycenaean pottery has been found in this level that matches with the type and the style of the pottery of the invaders from mainland Greece. Also found in this level were three arrows and some human remains.

Troy VI is Blegen's city of grand houses; here he found a single Mediterranean arrowhead but no remains. The earlier Bronze Age cities were thriving trading centers that traded horses, wool, and slaves. It was Troy II that Schliemann initially proclaimed to be the Homeric Troy. Hisarlik is now referred to as the archaeological site of Troy.

In over 5,000 years of history, the archaeological site of Troy has revealed nine successive

➤ HOMER'S TROY

Prior to German archaeologist Heinrich Schliemann's excavations in the 1870s, the city of Troy was believed to be mythical, as it was based on Greek poet Homer's epic, *The Iliad*. Renowned for its importance in the Homeric tale of the Trojan War, Troy was perceived by most educated Europeans of the nineteenth century to be a purely fictional place, its existence unsubstantiated by any tangible evidence. Schliemann's discovery of Troy, along the Dardanelles in Asia Minor, and later excavations demonstrated that a total of seven cities had been founded in the same location over a long span of time. Notable for its location on an important geographical crossroads of the ancient world, Troy served as a center for the trade of tin between Asia and Europe. Moreover, as a vulnerable trade center caught between the Greeks to the west and the myriad peoples of West Asia, Troy and its successor cities were constantly destroyed and rebuilt.

—Abraham O. Mendoza

View of the ruins at the archaeological site of Troy in present-day Turkey. During the late nineteenth century, an amateur archaeologist named Heinrich Schliemann succeeded in locating the site of the ancient city of Troy. Later excavations have shown that the ancient city that occupied the site was destroyed and rebuilt many times over the centuries. (Jon Eben Field)

cities, but not one of them can clearly be defined as Homeric Troy. Four arrowheads and a few human remains cannot be construed as evidence of the fiercely fought siege of a ten-year duration. However, excavations continue with both new and old technologies, and it appears that the archaeological site of Troy has a lot more secrets to reveal. In 1998 the archaeological site of Troy was listed as a United Nations Educational, Scientific and Cultural Organization (UNESCO) World Heritage site.

Ugarit and the Levant—Public Architecture

Small kingdoms ruled by petty kings dominated the Levant throughout the Bronze Age. Unlike the Egyptians to their south or the Hittites to their north, the kings of the Levant never successfully united to form a large state. Lying as they do along the trade routes between Egypt, Anatolia, and Mesopotamia, much of their culture was influenced from the outside. This is especially true of the royal elite, who consciously styled themselves after the great kings of Egypt or Mesopotamia. Even so, an indigenous cultural uniformity is evident in the public architecture of the Levant and western Syria, the region known as the Syro-Palestinian sphere.

Temple architecture is the most marked example of a long-lived and widely adopted cultural expression. At Levantine sites such as Jericho, Hazor, and Beth Shean and Syrian sites such as Ebla, Emar, and Ugarit, small free-standing temples built with antechamber and cella on axis

are the norm. In northern Syria this is the classic Syrian *in antis* type, a long-roomed cella with two side walls projecting forward to form an enclosed porch. In the southern Levant the cella is often broader or almost square and has pillars, but the two types are clearly related. This Syro-Palestinian temple form has a long history in the region ranging chronologically from the Neolithic period down to the early Iron Age.

In the Middle Bronze Age many Levantine and Syrian sites display marked similarities in their defensive systems. At this time, the eighteenth to seventeenth centuries BCE, most Levantine sites built massive fortifications with great earth ramparts often topped with a casing of stone, called a glacis. In addition to the strong ramparts, Levantine sites such as Shechem and Hazor, Alalakh in the north, and Ebla in the east built nearly identical two-chambered gates flanked by massive towers. The lower courses were often encased with stone slabs for extra strength, a technique also used in Syrian palaces.

More examples of a shared Syro-Palestinian architectural tradition can be seen in the palatial architecture of Late Bronze Age kingdoms. Several design and planning features are shared at the palaces of Megiddo, Lachish, Alalakh, and Ugarit. In all cases, the palaces were mostly square buildings built around a large rectangular court. Reception rooms within the palace were almost always approached through pillared entryways. This arrangement of an antechamber and pillared entrance was first found in the fifteenth-century BCE palace at Alalakh, was used again in the palaces of Ugarit and Megiddo, and became the main feature of the Iron Age Syrian palaces called *bit-bilanis* (portico house).

Ugarit is the best preserved and most splendid of these Late Bronze Age palaces and magnifies on a large scale the features of the smaller southern examples. The palace itself was built and used in the fourteenth to thirteenth centuries BCE. It was multistoried and covered an area of at least 6,500 square meters. Unlike the other palaces of Syria-Palestine, Ugarit was constructed mostly of stone and not mud brick. It was thoughtfully constructed and included amenities such as planted garden courtyards and a water system running through the palace in canals under the floors. Even in its own time, Ugarit was considered one of the wealthiest sites in north-

THE ART OF DEFENSE IN SYRIA-PALESTINE

Toward the end of the Middle Bronze Age there was an intensification and standardization of defenses at many Syro-Palestinian sites. Many cities in the period from circa 1800–1600 BCE spent considerable effort on new and improved fortifications. This can be seen in the wider city ramparts that now included very steep earthen ramparts or stone- or lime-lined glacis and large two-chambered gates. The fortifications attest to a highly politicized and competitive environment in the Levant at this time. The modifications in city defense also reflect changes in military technology and warfare. The new wider gates with ramps provide better access for the latest in military technology, the horse-drawn chariot. The ramparts or glacis helped to defend against siege techniques such as tunneling below city walls or attacking the walls on ladders. It also counteracted the latest military innovation: the use of the battering ram.

—Susan Helft

ern Syria-Palestine. Rib Hadda wrote to Egypt of Ugarit, “See, there is no mayor’s residence that can compare with that at Tyre. It is like the residence at Ugarit. Extraordinarily large are the riches there.” The fiery destruction of circa 1200 BCE that brought the city to its end also preserved many of the riches of the royal palace at Ugarit. Archaeologists recovered some of the finest gold and ivory work of the Late Bronze Age from there. The objects found in the palace showed that Ugarit had very close ties with the Aegean to the west and the Egyptians to the south.

Near Eastern Tells

Most archaeological sites excavated in Mesopotamia and the Levant are of a particular type called a tell. A tell is simply a large mound (*tell* is the Arabic form, and *tel* is the Hebrew form). These tells vary considerably in size, but most range from 7 to 20 acres in size, although tells as large as 200 acres do exist. A typical tell in Israel was occupied for about 1,000–2,000 years and contains remnants of all of those years of occupation. A ruin (or *khirbet* in Arabic) is a site that is only occupied very briefly, maybe for 100 or 200 years, and is usually quite a bit smaller than a tell.

Tells form because people in the ancient Near East tended to build their cities on top of older settlements. It may seem strange that people would have kept building cities higher and higher instead of just moving to another location

Tell at Beth Shean, Israel. (James Emery)

(like the ancient Egyptians did), but in fact it is quite a logical practice given the environment of the Near East. Cities need to be located near a stable water supply and need to have sufficient arable land to produce food for the inhabitants. Since locations where both of these conditions are met are limited, it was worthwhile to build cities in the same areas, over and over, basically as long as the land remained arable and water was present.

Because of this conservatism, fixed trade and communication routes quickly became entrenched. So, if an older site had been located along a major trade route, it was worthwhile to build a new city in that same location since the transportation and communication infrastructure may already have been present. Building on high ground also presented certain benefits. The city can be more easily defended from up high, and invaders can be seen from farther away. Flooding and other natural disasters are also less problematic from up above.

—Kevin M. McGeough

➤ WHY ARE ANCIENT SITES BURIED?

Almost all archaeological sites are buried. This seems strange to our own lived experiences of the world because the processes through which an entire city can be buried occur at a very slow rate over hundreds of years. Rivers gradually expand and contract (dependent on varying precipitation levels), leaving deposits of silt and gravel over a site. Wind can blow unconsolidated material (such as soil) over a site; in places such as Egypt where there is little plant life to anchor the soil, these aeolian deposits can be quite substantial. Forest droppings (such as leaves and pine needles) eventually build up and decay, forming humus that can completely cover a site. Gravity also has an effect; material tends to roll downhill over time, and this can gradually lead to a buried site. Natural catastrophes can also bury sites. Floods can leave up to 3 feet (1 meter) of silt on a site, and volcanoes can cover a site almost completely. Humans also play a role in burying sites, especially through construction. Before modern construction equipment allowed for a building foundation to be dug rapidly and all of the previous material removed, most builders would simply knock down the older material, rake it over, and fill in any open spaces with construction fill, in the process burying the ancient site.

Levantine Houses

The form of the Levantine house varied according to conditions of geography, economy, available materials, and constraints of space. Both

rural and urban settlements held multistory structures, although few examples have been recovered. Wealthier homes were made of better-quality building materials and had more rooms and decorative elements, but the majority of the population lived in simple structures. The basic house, which would have served a sedentary family supporting itself through a mixture of agricultural production and animal husbandry, included living, working, and storage space for both people and animals.

Wood, stone, and mud were the most common building materials. In the hill country, both foundations and superstructures could be built from stone. Elsewhere, where stone was less plentiful, walls were built of sun-dried mudbrick with stone foundations or entirely without stone. Straw was used in the brick to bind the mud and provide strength. Mud plastering prevented erosion of the brick and could be whitewashed. Doors, windows, and ceiling supports were made of wood. Room width was limited by the length of available timber, but this could be extended by the judicious placement of pillars to support shorter beams. Smaller branches spanned the ceiling beams and were covered by a thick mud plaster to create a stable second floor or roof.

Typically the ground floor housed animals and heavy items and provided work rooms, while the upper stories were intended for living accommodations and additional light storage. Roofs (accessed by built-in stairs or ladders) were flat and could serve as a work, sleeping, or storage space in dry seasons. Beaten earth floors were frequently plastered or covered by mats, carpets, or flagstones. Windows were likely small and restricted to use on the upper stories for purposes of safety and privacy. Cooking took place either indoors on the ground floor or outdoors in courtyards.

Structures were either rectilinear or curvilinear in plan. Most rounded house plans went out of use by the Early Bronze Age IV/Middle Bronze Age I (ca. 2300–2000 BCE), although some continued to be used at the fringes of sedentary society. The curvilinear layout was less conducive to use in areas of dense population, such as urban settlements. Rectilinear structures allowed for a more economical use of space. They could fit tightly adjacent to one another,

➤ PHILISTINE HOUSES

Archaeologists have discovered several examples of Philistine domestic structures. Although some scholars continue to debate, most agree that the Philistines, the biblical enemy of the Israelites, were originally an Aegean people who migrated to the shores of the Levant around 1185 BCE, bringing their distinctive culture with them. The lack of similarity to the layout of the ubiquitous Israelite house supports the interpretation that the Philistines were an intrusive culture in the region. Their rectilinear houses frequently included a large room with a central pillar (likely support for a second story) and a hearth for cooking and heating. Rooms of varying size and function were arranged around this central living space. An adjacent exterior courtyard appears to have served for baking activities and garbage disposal, a pattern of use found throughout Near Eastern settlements. Activities such as the spinning of thread and the weaving of cloth on a vertical loom took place inside the residences.

—Adam Aja

even sharing walls. The layout of structures demonstrates that the residents did not have a fixed plan but instead built to suit the needs of the family and the constraints of the space allotted to them. Over time, individual structures could be altered to add, remove, or subdivide rooms, possibly for rent and sale or for issues of inheritance. By the Late Bronze Age (ca. 1550–1200 BCE) the common Levantine house consisted of several rooms placed to the side of a courtyard. The Iron Age I (ca. 1200–1000 BCE) saw the development of a nearly standardized rectilinear house plan, variously identified as the Israelite house, the three- or four-room house, or simply the pillared house.

The use of the pillared house appears to have spread from the central hill country and Galilee to be used everywhere in rural and urban settlements. Discussion of a standard layout should not obscure the frequent variation witnessed in the numerous Iron Age examples. Generally, the pillared house displayed a large central room, divided from two parallel side rooms of equal length by rows of pillars. At the back, a

broadroom for storage spanned the width of the building. Often the space between the pillars was filled to create walls. The designation “four-room” describes the plan of the ground floor, although the rooms of the upper floors should not be forgotten. Previous reconstructions did not include a second story or left the central room unroofed. The central pillars supported a ceiling and were easily spanned by available timbers. Flagstone-covered floors in the side aisles provided a durable surface for stabling animals and facilitated the mucking out of the stalls.

The Palace of Mari

During the Bronze Age (3300–1200 BCE), Mari (present-day Tell Hariri) was an important trading center because of its position at a major crossing point on the Euphrates River. Mari lies on the eastern border of present-day Syria, and in antiquity it controlled the trade between the Syrian states to its west and south and the southern Mesopotamian states to its southeast. Mari’s intermediary position between the Levantine coast on the one hand and the cities of Babylonia on the other hand certainly influenced its political and social culture. Nowhere is this more evident than in the large palace at the very heart of the city.

Even in antiquity the palace at Mari was famed for its size and beauty. Other kings specifically came to Mari to see the splendor of the palace as is attested by a letter to the king of Mari, Zimri Lim, translated by Dossin in 1937: “Thus says your brother Hammurabi [of Yamhad]: The king of Ugarit has written to me as follows: ‘Show me the palace of Zimri Lim! I wish to see it.’”

The palace of Mari was quite extensive, covering at least six acres of the city and occupying a ground area of about 26,910 square feet (2,500 square meters). The first floor had more than 250 rooms, and at least part of the palace had a second story. The palace is called the Palace of Zimri Lim because Zimri Lim was the last known ruling king at Mari, but the palace was actually constructed over a period of about 300 years. The building itself served as the nexus of the city from the Sumerian period of circa 2100 BCE to the time of Hammurabi (ca. 1750 BCE). The palace is laid out on a well-known Mesopotamian plan of large square courtyards with adjacent long reception rooms. The Mari palace centered around two main courtyards that were open to the sky. One of these, we are not sure which, was called the Court of the Palms and was probably planted with trees and a garden. Spanning out from these courtyards are royal

➤ THE MARI ARCHIVE

Thanks to the roughly 20,000 tablets found at Mari, archaeologists have a very good idea of life in the palace of Zimri Lim. Even mundane events were recorded by the king. One recorded that a lion was captured on a rooftop in the city and another that locusts were sent to the king (perhaps as food). In another letter Zimri Lim gives advice to his wife not to let the palace women drink from the cup or sit on the seat of a certain Nanna who has a very contagious disease. The palace was very luxurious for its time. We know for instance that the king had ice brought down from the mountains to cool his drinks in the summer months. We also learn about the work of palace singers, weavers, cooks, scribes, and doctors, all attending to the needs of the kings at the palace.

apartments, a throne room, a chapel, living apartments, kitchens, storerooms, workshops, bathrooms, and an archive.

The palace at Mari is the largest palace in Syria excavated so far. It is best known today for the paintings and sculpture found there over the course of excavations. Painted walls have survived from the major courts and adjacent shrine (rooms 131 and 132). They portray processions of men and animals in typical Syrian-style clothing. The most famous of these paintings is called the Investiture of Zimri Lim. It shows the king receiving the rod and the ring of kingship from the god Shamash in a vibrant garden scene with mythological creatures. In the adjacent room (room 65), either a shrine or the throne room, two large sculptures of the “goddesses with flowing vases” flanked the entrance. These were extraordinary because they actually piped water through the statues so that it would flow out of the vases that the goddesses held in front of them.

Ziggurats and Gardens of Mesopotamia

Uruk, probably the world's first city, had at its heart two sacred areas: Kullaba and Eanna. Throughout the fourth millennium BCE Kullaba was focused on a single shrine, the White Temple, built from the start on a slight platform. These were repeatedly reconstructed, increasing in size and reaching their final version around 2900 BCE, when the temple was raised on a platform that was 14.2 yards (13 meters) high.

The tripartite plan that had characterized the White Temple became standard in the third millennium. While the normal low temple was the home of the deity, some (high) temples were

Ziggurat at Ur, an important Sumerian city in ancient Mesopotamia, photo from 1932, before restoration. (Library of Congress)

raised on platforms: these may have been regarded as portals through which the deity might descend to Earth as well as a means by which priests could come closer to the gods. This practice reached its climax when the first Ur III king, Ur-Nammu (2112–2095 BCE), created ziggurats (sacred pyramids) at Ur, Eridu, Uruk, and Nippur.

Ziggurats were constructed of solid layers of sundried brick, separated at every seven courses by a layer of reed matting as protection against rising damp. Weep holes set at intervals and internal drainage shafts also served to keep the structure dry. A thick facing of baked bricks protected the exterior. The Ur III ziggurats, epitomized by the well-preserved example at Ur itself, consisted of three staged tiers, sloping inward, with a platform at each stage accessed by a triple stair on one side; some later examples, such as that at Dur-Sharrukin (Khorsabad), were approached via a spiral ramp. The platform on the summit bore a building, probably a shrine.

Ziggurats became a regular feature of sacred precincts in subsequent periods. A block of solid brick masonry, wind scoured but still monumental, remains from the Kassite ziggurat in Dur-Kurigalzu (Aqar Quf), while in neighboring Elam the short-lived city of Al-Untash-Napirisha (Choga Zanbil) was centered on the largest surviving ziggurat, still substantially preserved; this differs from the Mesopotamian examples in form, having internal rooms in the ground tier and four internal staircases. The tradition reached its zenith with the famous ziggurat of Marduk (the

➤ GARDENERS

Gardeners are often mentioned in early Mesopotamian texts. According to legend, Sargon of Akkad (ca. 2334–2284 BCE) was the son of a priestess who, when he was born, cast him adrift on the river in a reed basket. He was rescued by Aqqi, a water carrier, who raised him as a gardener. In the eighteenth century BCE gardeners were among the many people listed as working for the palace at Mari on the middle Euphrates. Specific reference is made to the employment of blind people: gardening was apparently one of the range of occupations they undertook. In the previous century, Erra-imitti, king of Isin, had chosen a gardener, Enlil-bani, to act as his substitute, a device intended to avert from the real king evil that was forecast. This failed. Erra-imitti himself died, and Enlil-bani became king in reality, reigning for 23 years.

—Jane R. McIntosh

Tower of Babel) in first-millennium Babylon, which had seven tiers. Ziggurats were apparently painted; the traditional colors for seven-tiered examples were, from the bottom up, white, black, red, blue, orange, silver, and gold.

When Leonard Woolley excavated the Ur ziggurat, he believed he had found evidence that the tiers had been planted with trees and vegetation, the model for the later Hanging Gardens of Babylon. This theory is no longer accepted. Providing a daily supply of water for such plants would have been an impossible task; moreover, the combination of water and roots would soon have destroyed the mud bricks of the structure. Texts make no reference to plants on ziggurats, and more recent investigations have found no evidence of such gardens.

In contrast to Kullaba, the Eanna precinct at Uruk developed in the fourth millennium BCE as a diverse complex of shrines, courtyards, and other religious structures. The public spaces between the buildings, epitomized by the Mosaic Court with its cone mosaic walls and pillars, were probably as much the focus of religious activities as were the buildings' interiors. Cisterns and conduits found here may have supplied water for trees and plants in some of these open

spaces, the beginning of the practice of creating gardens in palace and temple courtyards.

Not all Mesopotamian rituals took place within the temple precincts. An important part of many religious festivals was transporting the god's statue from his home in the temple to a garden within or outside the city.

Gardens played an important role in Mesopotamian life. The description of Uruk in the days of the semilegendary King Gilgamesh, who may have lived around 2600 BCE, mentions that a major part of land within the city's walls was garden (date orchard). A cuneiform tablet dated around 1300 BCE bears a scale plan of the city of Nippur, carefully labeled with measurements. It shows the city's walls and gates, the Euphrates River and its canals, a number of temples, and one large area in the south labeled "garden in the city."

Both in the cities and their suburbs and in the land surrounding villages, gardens were used to raise fruits and vegetables to complement the cereals grown in the fields. Gardens were often located on river levees or along the banks of streams and canals, where they could be watered regularly, either by hand or by lifting water using a shaduf.

Often the plants were grown in a highly efficient shade-tree garden, the origins of which are described in a Sumerian myth. There was once a gardener, Shukalletuda, who could not grow his plants because they were burned up by the sun and covered with dust by mountain winds. After long thought and study of divine matters, he devised a way of overcoming these problems, planting a *sarbatu* tree to provide perpetual shade.

Sumerian shade-tree gardens usually used date palms rather than *sarbatu* (probably the Euphrates poplar). Tall date palms provided day-long shade from the hot summer sun, creating a microenvironment of cooler temperatures and higher moisture. Shorter fruit trees such as apple and pomegranate were planted beneath the date canopy, and vegetables, herbs, and spices were planted at ground level. Manure was sometimes applied to increase productivity. Similar gardens shaded by other trees were popular farther north. Shade reduced the evaporation that would normally have occurred when plants were watered in the summer heat. Other trees in the

garden might include tamarisk, grown for its wood, as well as figs, pear, plum, cherry, and mulberry.

In the third millennium the plants grown included various pulses, cucumbers, garlic, and onions; later the range increased, including beetroot, turnip, leeks, mustard, cress, radish, lettuces, fennel, coriander, marjoram, saffron, fenugreek, rue, mint, rosemary, melons, cumin, and watercress. Grapes were also grown in shade-tree gardens, trained along trellises or from trees. Olives were grown in Assyria but did not thrive in Babylonia.

Date palms were not only for shade. Dates, rich in vitamins and high in carbohydrates, were the chief fruit grown in Babylonia. They were hand pollinated from at least the time of Hammurabi, allowing growers to raise mainly the fruit-bearing female trees. Their young sprouts could be eaten as a vegetable, and the palms yielded leaves for making roofs, baskets, and mats; bark fibers for making rope; and, at the end of their productive life, timber. Date palms represented a considerable investment, as they did not bear fruit until their fourth or fifth year and reached full productivity only around 25 years.

While growing vegetables, fruit, and herbs was important for the Mesopotamian economy, gardens were not merely for producing food but were also shady places of relaxation where lovers or other people might meet in privacy and meals could be taken.

The courtyards of palaces and the precincts of temples were probably often furnished with trees and gardens. The Ur III king Shulgi (2094–2047 BCE) claims in his inscriptions to have planted gardens, and evidence of gardens comes, for example, from the palace at Mari where date palms were planted in at least one of the courtyards. Texts from Mari show that the king and his entourage often ate in the garden. Excavations in the palace at Ugarit (dating from the second millennium, like Mari) revealed traces of a garden in one of the courtyards with a pool near the center; loose earth suggests that there were plants around the courtyard and possibly a tree in its center. Another large courtyard in the eastern part of the palace contained a walled garden.

Tiglath-Pileser I (1114–1076 BCE) may have been the first of many Assyrian monarchs to cre-

ate a garden planted with trees brought back from his campaigns in foreign lands, including cedars, boxwood, and oaks. He also collected exotic animals: herds of horses, deer, gazelle, and ibex stocked his park—along with four Syrian elephants he had captured in the Habur region.

Mesopotamian Houses

Early experimentation with house structure in Mesopotamia largely disappeared by the second millennium BCE, when the courtyard house emerged as the predominant choice for both rural and urban domestic architecture. Some of the largest areas of domestic housing have been excavated at the urban sites of Nuzi, Nippur, Ur, Sippar, and Babylon, but additional examples have been identified including some at smaller rural sites in the Hamrin. The typical courtyard house had several rooms arranged around a central open courtyard, which provided light and air to the surrounding rooms. Residents used these rooms for storage and living space but also had special rooms for use as bathrooms or kitchens. The kitchen, identified by the presence of an oven, was often located in the corner of a house. Poorer structures may only have had one or two rooms in addition to the courtyard, which could have served as the cooking and baking area. The stairwells that have been identified in some buildings may have only led to a roof rather than a second story, although the roof in Near Eastern climates typically could be

➤ A NEIGHBORHOOD AT UR

The excavations of Leonard Woolley at Ur exposed one of the most illustrative examples for early second millennium domestic architecture. The neighborhood of narrow, meandering streets possessed generally small structures (under 100 square meters or 119.6 square yards) that included storefronts, shrines, and the homes of both wealthy and poor. Although there was no standard size or layout for the buildings, the structure at Woolley's so-called #3 Gay Street serves as an example of the ideal house type. Residents could enter from the street by passing through a small entrance chamber, which led into a central bricked courtyard. There were no windows in the first story since the courtyard would provide light and air to the living rooms, storage spaces, kitchens, and bathrooms arranged around and opening onto it. Interior walls were plastered and whitewashed, and the foundations were constructed of baked mud brick to protect the walls from the damp. A stairwell gave access to the second story.

—Adam Aja

used as an additional functioning room for the house, providing storage or sleeping space and a well-lit activity area. Wealthier urban homes would often have a small entrance chamber between the street and the courtyard. The doors of this chamber were offset to obstruct or obscure the view of the courtyard from the street, thus providing an additional level of privacy. It is suggested that buildings with direct access to the courtyard from the street might have housed animals.

Mud brick was the most common construction material in southern Mesopotamia. Even in northern Mesopotamia, where stone was more common, builders often opted for the inexpensive and readily available mud alternative. By the second millennium, bricks were typically made by packing mud into wooden molds and leaving them to dry in the sun. To prevent cracking, builders used chaff as a temper for bricks with high clay content or straw as a binder for silty

bricks. Additional mud served as the mortar. Mud-brick walls supported wooden roof beams without the aid of any pillars. Smaller timbers or branches spanned the roof beams, which were covered by brushwork or reeds and sealed with a thick layer of mud plaster. Builders used wood for doors, window frames, and lintels. Doors pivoted in stone sockets. Mud plaster, whitewash, or paint covered some walls. Gypsum (more common in the north) or lime may have been added to the mud plaster to act as the whitewash, although it was little used in domestic architecture. The reeds plentiful in the wetlands of southern Mesopotamia served several functions including mud-brick temper, mats, curtains, and fencing. Builders frequently added harder kiln-baked brick for foundation courses to provide some stability and protection from rising damp. Baked brick was also used in paving, drains, water basins, and thresholds. In later periods and in wealthier structures, bitumen was used to waterproof drains, toilets, basins, and lower damp courses. Given the scarcity of wood and stone, building components constructed of these materials were frequently rescued and recycled when houses were rebuilt. Rebuilding a house (every 60 years or so) often brought some changes to the layout, either by dividing a room or expanding the structure to incorporate areas that had previously been considered exterior spaces.

Changes in family size may have necessitated some alteration to building layout. A household would most likely have consisted of a single simple family related by marriage or blood or may have included an additional generation, slaves, or animals. Houses could be divided to accommodate the families of several sons (as texts at Nippur indicate), with rooms being altered for different uses. Alternatively, individual rooms might be sold off and the structure reconfigured to change the access to the room. Family tombs were often located directly under the homes. An eldest son's favored inheritance or retention of the house might have been tied to his maintenance of rituals for the dead ancestors. Homes, such as those at Ur, were often equipped with a small shrine or cultic niche, perhaps designated for this purpose.

Monumental Architecture in the Indus Valley

One of the most puzzling aspects of the Indus Valley civilization (the ancient Harappans) is the lack of evidence for public structures such as palaces or temples, typical of other urban societies in the period between 1000 BCE and 300 CE. Perhaps these kinds of structures have not yet been excavated, or perhaps buildings that have already been excavated have not been properly identified. Some examples of public architecture have been identified, although the functions of these buildings are heavily debated by scholars.

The least controversial types of public architecture are the fortifications common to the cities of the Indus River valley. These fortifications were made of mud brick, as were the gates that allowed access through the walls. The cities themselves were surrounded by walls; smaller walls also separated subsections of the cities.

Most controversial are the so-called granaries excavated at Mohenjo-daro and Harappa. The granary at Mohenjo-daro was extensively excavated in the 1950s by Mortimer Wheeler, who unfortunately did not record the types of artifacts that were retrieved from the structure. However, excavation records do point out that no remnants of grain were recovered from the structure, which perhaps should have indicated to him that this was in fact not a granary! The structure itself is quite large, about 165 × 88 feet

➤ TOWERING WELLS

Visitors to Mohenjo-daro may be misled by the large, circular mud-brick buildings that rise high above the plain. These structures look very much like watch towers or medieval European castles. In fact, these are ancient wells excavated by archaeologists. In ancient times the wells would have extended deep underground, with the sides buttressed by the mud-brick structure. Only the very top of the well would actually have been visible aboveground.

—Kevin M. McGeough

(50 × 27 meters) in size, and is divided into 27 rectangular or square blocks. While most no longer accept that this was a granary, there is little evidence to point to its actual use. The granary at Harappa is equally suspect. This building is about 165 × 130 feet (50 × 40 meters) in size and built on a mud-brick foundation. A corridor 23 feet (7 meters) wide runs through the center of the structure. The corridor separates two rows of six rooms. The building does not resemble the “granary” at Mohenjo-daro except in one way: no evidence for grain was retrieved from it either! So while the “granary” at Harappa was certainly a large public building, it was likely not a public granary. Other large buildings have been excavated at Harappa, Mohenjo-daro, and other sites and are varyingly called assembly halls or college halls, acknowledging that these buildings would have facilitated public gatherings but that no evidence remains to indicate the precise function of these structures.

A less controversial but nonetheless stunning piece of monumental architecture is the Great Bath at Mohenjo-daro. This may be the earliest public water tank in the world. It is 40 × 23 feet (12 × 7 meters) wide. Two wide staircases lead down to a ledge that surrounds the bath. People would have been able to walk around the ledge, gaining access to the water without actually getting wet. The floor itself is water-tight. It is made of tightly packed mud bricks and gypsum plaster. The walls of the bath were reinforced with bitumen (a tarlike substance with waterproofing

characteristics). There is not much evidence for public bathing here; it was more likely used as a supply of fresh water.

Urban Planning in the Indus Valley

The ancient cities of the Indus Valley (the Harappan culture) display an orderly design and may reflect some of the earliest conscious urban planning (as opposed to a laissez-faire strategy of constructing buildings beside earlier building without any overall strategy for the shape of the town). The basis of this urban design is the layout of streets along the cardinal directions. Careful astronomical observations must have been made in the initial laying out of major city roads. The major roads form rough grids with north-south and east-west axes.

▶ THE HOMOGENEITY OF INDUS URBAN DESIGN

Much is made of the relative homogeneity of urban design in the cities and villages of the Indus Valley. The traditional accounts of the sites suggest that the people of the Indus Valley shared a common sensibility of what their cities and houses should look like. At first glance, this certainly seems to be the case. The construction materials are the same at most cities (even the size of bricks used is relatively consistent) and domestic architecture in general looks relatively similar. On closer examination, these similarities may only exist at a surface level, as the spatial relationship of structures within the cities varies. Still, the sites do share general features pointing to an overriding architectural sensibility that could be called Harappan or Indus.

—Kevin M. McGeough

Mortimer Wheeler, who excavated Mohenjo-daro in the 1950s, described the city plan as a gridiron layout, believing that the construction of buildings in between the roads was constrained by formal desires to retain a grid structure. This viewpoint has been questioned recently, since the actual evidence from Mohenjo-daro does not seem to support this view. In fact, the buildings in between the major roads as well as the minor roads appear more haphazard, looking more like a large interlocking net of varying size than a formal grid. The major roads were laid out with a strict cardinal orientation, but the rest of the construction was not constrained by this orientation per se. Using the roads as boundaries, structures were built as space and resources would allow, shifting over time as they were renovated, destroyed, and rebuilt.

Urban design based on an initial large-scale plan and followed by ad hoc construction as the need arose is also apparent in the extensive sanitation systems. The initial laying out of a sewage system would have required extensive planning and cooperation among the inhabitants of the city. Once laid out, the sewer system could be altered with minimal effort. It must be presumed that some sort of infrastructure (or at least formal rules) existed to provide maintenance of the sewage system and handle dispute resolutions for neighbors sharing the same drains.

The domestic architecture at Harappan sites is also indicative of a shared sense of what a house should look like. Mostly made of mud brick and wood, houses were built with the same general principles. The center of the house would be a large courtyard with several rooms opening into it. The houses were at least two stories tall; upper roofs were probably built of wooden beams and straw, although none of these have survived. Doorways to the houses were located along side streets and alleys and not on the major roads. Windows were common; shutters or lattices of wood provided some privacy.

Shang Cities

The layout of Chinese cities is remarkably conservative. Until the rise of the communist government in the twentieth century of the modern era, the ideal Chinese town was enclosed by a rectangular wall complex. Within the major wall system, Chinese cities were further subdivided into smaller sections, creating inner cities and separate complexes. This conceptualization of the city as walled space was already present to some degree in Neolithic China and is fully apparent in Shang period urban planning.

Throughout the period of the Shang kings, the establishment of cities was part of the formal strategy of asserting the dominance of the monarch and securing political, economic, and military force throughout the kingdom. The walled cities built under the auspices of the Shang ruler acted as fortresses throughout the heartland of the kingdom, as both real loci of military power and powerful symbols of the military dominance of the king. The capital city of the Shang king varied with shifting political currents (especially with the vacillating power of many of the minor lineages).

Archaeological excavations have provided a wealth of information on Shang cities. Many scholars have attempted to connect place-names from the ancient historical accounts of the Shang with archaeologically excavated sites. This is actually extremely difficult, as the ancient names of the archaeological sites have usually not been preserved. The standard practice is to refer to these Shang cities by their modern place-names, a practice followed here.

The site of Yanshi is one of the likeliest candidates for an early Shang city. It is a relatively small city, surrounded by an imposing wall 52–82 feet (16–25 meters) thick and 3–7 feet (1–2 meters) high. Within this wall is a second wall, differentiating an inner and an outer city. The

outer city wall has seven narrow gates and would have been a strong defensive structure. Within the inner city is a palace complex.

Zhengzhou dates slightly later and is a larger city, with a wall that was 66 feet (20 meters) thick and 33 feet (10 meters) high. Within the walls is a large palace complex (in the highest section of the city); the remains of human sacrificial victims are interspersed throughout the palace complex. The residential areas of the city display class differences, with elite homes as well as very small homes of a poorer group. Bronze workshops were identified within the city walls, as were two hoards of bronze artifacts. Cemetery complexes were also found in the city.

Since 1928, excavations at the site of Anyang, on the Huan River, have revealed much about Shang civilization. Anyang has been identified as the last Shang capital city, Yin. Yin was inhabited during 1300–1050 BCE; the excavators believe that there were four major building phases within that time period. Only parts of the city wall have been located so far, and some contest that these are in fact parts of the city wall, but it is assumed that there was one. The palaces and temples of Yin are located in the northern part of the city, close to the river. The city itself consists of clusters of rammed earth foundations (called *hang tu*) upon which sat various structures. A royal cemetery and numerous sacrificial remains have also been located at Anyang.

Houses in Early China

Architectural tradition in China divides along regions determined and dominated by the great river systems, the Yellow River in the north and Changjiang River in the south. Along the middle course of the Yellow River rises the high and arid plateau of yellow earth that supported many of the splendid empires of the Chinese past, while the Changjiang River flows over 1,000 miles of fertile tract of flat plain where the ancients settled. Each region from very early times defined an architecture essentially its own and forecast later phases of Chinese architecture.

Each region has its prototypes: dwellings cut into earth in the north where the land is high and shelters erected on trees in the south where the underground water is high. The building materials were those most readily available for constructing shelters: earth, wood, bamboo, and thatch. The main building material in the north is earth, and the main building material in the south is wood.

The architecture in the loess plateau has been distinguished by earthen dwellings, which still dominate the rural area in the region today, called *yaodong*. The earth-cut caves without architectural form and structural mass were made by digging into the hillside or terrace for space. The layout depends upon the geography of the land.

According to Chinese literature (*Huai Nan Zi*, ca. 120 BCE), Emperor Shun (ca. twenty-second century BCE) was the first to design buildings to allow his people to move away from caves. Archaeological excavations proved that early buildings in the Yellow River valley were mainly roofed and semisubterranean. At Banpo near Xian, the dug space was in general about 15–31 inches (0.4–0.8 meters) below ground level of the respective times, which became shallower in the later time. The dwelling units were circular or square in plan and had a diameter or side of 13–19 feet (4–6 meters); rectangular plans of housing areas up to a 1,076 square feet (100 square meters) appeared at later dates. The houses were timber structured and plastered with mud. The floors were prepared by pounding clay and then treated by burning for heating

*Multiple courtyard complex, Early Western Zhou.
(Joseph K. Crea)*

purposes into a continuous surface. This has led to its historical name, terracotta subterranean dwelling (*taofu taoxue*).

To protect the earthen walls, additional eaves were constructed by the Shang people. Moreover, to avoid attack by rain and groundwater, buildings were elevated; as Mozi (468–376 BCE) said, “build houses upon high platforms to avoid excess moisture.” The state architecture of the Spring-Autumn and Warring States periods was represented by wooden buildings on high platforms of rammed earth. The platform could be several levels, and the central part was usually higher than the surroundings, which might result in a multistoried appearance of grand scale. This type of buildings is traditionally called high-platform architecture.

Yellow earth is strong enough to bear heavy loads when dry, but excess water may cause it to expand and even sink or slide under a load, leading to building collapse. This problem was solved by ramming the earth. The platform, on a building site, was made by first digging a base in the ground 3–9 feet (1–3 meters) deep, then filling it with soil and ramming it to compact it layer by layer until the required height was reached.

The archetypal house of the Changjiang area was characterized by a wooden structure raised on posts, with a pitched roof and extended ridges. Many building remains of this type were found from a prehistoric site at Hemudu in Yuyao, Zhejiang Province, one of the most important centers of Neolithic culture. Bronze vessels bearing

incised depictions of a shelter on trees have been preserved to the present day to give picturesque evidence of the architecture. The pile dwelling was recorded as *ganlan* in historical books. This type of building is suitable for areas that are hot and humid, found in all parts of the geographical limits of the Changjiang River culture. Similar houses are commonly built in Southeast Asia.

A building compound excavated at Erlitou in Henan Province is believed to be a palace built in the late Xia dynasty (twenty-first to sixteenth centuries BCE). It is a courtyard compound bounded by roofed corridors all around. The palace consists of a gatehouse, a court, and a main hall. Facing south, the main hall is on a rammed-earth platform and is covered by a thatched roof. The building has eight longitudinal bays and three transverse bays. It measures 33 by 12 yards (30.4 by 11.4 meters), and each bay is a square whose sides each measure 4 yards (3.8 meters). The walls were of compacted earth within frameworks (*banzhu qiang*) that were plastered; the interior wall was decorated with paintings.

A courtyard complex of the early western Zhou, found at Fengchu in Shaanxi Province, is encircled by inward-facing buildings joined in a right angle on four sides. Typically orientated to the north-south, the main halls are laid along the axis: office in front and residence behind. A screen is in front of the gatehouse. The courtyard walls, gate, and screen certainly meant protection. In the compound there was a drainage system to allow storm water to drain away. The drainage design was responsible for the development of walled courtyards and walled cities in China.

Tsugaru, a Sociocultural Center in Ancient Japan

The Jomon age, the Neolithic age in the Japanese archipelago that laid the foundation for later Ainu and other indigenous cultures, emphasized shamanism as the primary governing system. Connected by trade and migration, ancient indigenous communities in northern Japan shared certain cultural practices with those in Siberia and across the Aleutians. Tsugaru, a peninsula in the prefecture of Aomori at the northwestern tip of Honshu, was a center of social, political, and spiritual exchange in the early indigenous history in northern Japan.

From time immemorial, Tsugaru has been a magnet for wrecked ships, flotsam, and refugees from all directions. Among its earliest settlers were speakers of an Ainu language. According to local oral tradition, the people of the region are the descendants of Asobe and Tsuboke; the word "Asobe" is a mispronunciation of the Ainu Ape "fire," and "Tsuboke" is originally *chupka* ("the sun"). The name "Tsugaru" may also derive from the Ainu word *chupka-un-kur*, the "People at the base of the sun," or "Easterners," as east remains the most important sacred direction for the Ainu.

A final Jomon period site at Kamegaoka (1000–300 BCE) in Tsugaru is one of the showcases of Jomon culture. The artifacts from Kamegaoka indicate a prosperous settlement with a rich ritual and ceremonial structure and considerable societal distinction. These include some of the early examples of female figurines nicknamed Jomon Venuses, often depicting a pregnant mother similar to those found in Siberia, such as Malta. These were deliberately broken or burnt before they were buried or disposed of, indicative of its use in fertility ritual. Kamegaoka-type potteries are characterized by elaborate asymmetrical shapes and designs, often compared to later Ainu decorative motifs. A number of similar sites in northern Honshu and Hokkaidô as well as mainland Northeast Asia indicate that a cultural relationship of some sort existed between these areas. Similarities in ritual objects used in shamanic performance, such as bent-nosed masks, also suggest a connection between the Jomon and ancient Siberia.

➤ WHO WERE THE JOMON?

The orthodox historical view of Japan assumes that the Jomon period was a historical Dark Age and that the Jomon populations were simple, primitive, and barbaric, lacking elaborate political arrangements comparable to the Yayoi state. In recent years, scholars have increasingly accepted the view that the Jomon populations shared a distinct culture and technology in the context of a complex sociopolitical relationship, managing territorial and economic matters without relying on a centralized political structure. In the hands of some proponents, however, this view retains nationalistic overtones, maintaining that the Ainu and the Ryukyu islanders, positioned on the geographic margins of present-day Japan, remain closest to the Jomon populations genetically, physiologically, culturally, and probably linguistically.

Nevertheless, a variety of locally occurring items of evidence suggests that certain characteristics of Jomon cultures extended beyond modern lines on the map. The Jomon populations were neither homogenous nor culturally uniform: they were constantly negotiating ways to relate to different groups in different areas at different times through various languages in the same way as any set of indigenous communities tied together by a stake in trade.

—Sakurako Tanaka

In the city of Aomori alone, approximately 200 Jomon sites have been confirmed, including several large stone circles. While many of these sites go back to the early Jomon, the Sannai Maruyama site is the best-known example of Jomon cultural development. This 5,000-year-old burial ground is considered to be part of one of the largest and most complex settlements from the Jomon period. The name “Sannai” derives from the Ainu expression *san-nay*, to “send downriver”; indeed, an Ainu village was known to have existed there until the nineteenth century. Sannai was a well-planned community, stable for 1,200 years from about 3200 to 2000 BCE, with a minimum population at times exceeding 500.

Sannai reveals the considerable technological achievements of the Jomon populations, evi-

denced in mass production (perhaps even surplus production) of pottery, lacquerware, jewelry, and stoneware as well as a high level of architectural and construction skill, including the use of large chestnut trees. Weaving and knitting characterize Sannai clothwork as well as sewing and perhaps even stitching, as countless needles made of animal bone have been found.

The Jomon inhabitants of Sannai were not simply a hunting and gathering people but were sedentary and affluent forager-fisher-farmers with ample access to sea and land resources. They foraged and farmed gourds, beans, burdock, perilla, flax, and millet and even farmed forestry resources by artificially creating chestnut forests around the community. There was also some level of urban planning to sustain the population within the limits imposed by ecological balance, evidenced by the use of Jomon feet, a measurement unit; the construction of paved roads with pits; and a well-planned waste disposal system.

The exchange with outside traders was an essential aspect of social sustenance. The Sannai site contains jade, amber, asphalt, and obsidian stones brought in through water-based trade from other regions across oceans and mountains. To accommodate the trade traffic, Sannai has an arc-shaped main public road 1,378 feet (420 meters) long running east-west, leading to and from the water. The tombs and large mounds are a highly organized part of community design and planning, indicating the development of social stratification and the possible emergence of slavery and/or outcast classes.

Complex ritual structures and belief systems interacted with their ecological situation and limitations at the Sannai community. The numerous finds of elaborate ritual objects, particularly of large female figurines and the evidence of careful urban planning that appears to have been carried out under the influence of a developed cosmological scheme, is all but impossible to explain without assuming a highly developed ceremonial and religious life on the part of the people who lived there.

Stonehenge

Stonehenge is an ancient monument of standing stones in the Wessex chalklands of southern England. Known as the place of hanging stones, it has captured the minds and imaginations of humans for thousands of years. The site consists of approximately 162 large stone blocks surrounded by an earthen enclosure and external ditch with a single opening to the northeast. The chief construction materials are sandstone sarsens (stone blocks) and bluestones, which originated from different geological sources and were manually transported to the site. The demanding assembly of Stonehenge occurred over a number of centuries and required substantial labor forces, skillful engineering, and the management of numerous resources. While its intended purpose is not known with certainty, Stonehenge probably played a central role in the expression and organization of communal beliefs, values, and ritual activities.

The emergence of henge monuments (stone monuments) in Britain marks a profound shift in the structure and organization of Neolithic communities. During the Early Neolithic, chamber tombs and long barrows frequently contained communal burials and collective mortuary deposits, which Harding takes as indicating the egalitarian organization of society and the importance of ancestor worship. By the Late Neolithic, communal burials were abandoned in favor of individual interments with discrete deposits of new and diverse material goods, denoting the advent of social stratification. The emergence of social ranking and overt changes in religious practices corresponded with the appearance of henge monuments, which provided alternative arenas for the participation in and organization of ritual activities.

Stonehenge is composed of a series of nested stone structures. The outer sarsen circle supports

Megaliths (large, ancient stones) constituting the circular monument known as Stonehenge on the Salisbury Plain near modern-day Wiltshire, England. (Corel)

a number of horizontal lintels that bridge the crowns of adjacent stones, only half of which survive from antiquity. Moving into the center of the circle, five autonomous trilithons—each comprised of two massive standing stones and a lintel—are arranged in a horseshoe formation that opens toward the northeast entrance of the enclosure. Igneous bluestones encircle the trilithons and line the interior area of the horseshoe. A handful of autonomous sarsens are positioned throughout the henge and may have fulfilled particular roles. Among the most important are the Heel Stone, located beyond the northeast entry of the enclosure, and the Altar Stone, located at the interior apex of the trilithon horseshoe.

The sarsens were obtained from a natural sandstone outcrop near Avesbury, approximately 19 miles to the north. There the stones were lifted from the ground with wooden poles and roughly shaped before transport. Crude breaks were probably controlled through fire-setting, which involved the repetitive application of fire and water. Sarsens were transported to the construction site with a series of ropes and wooden rollers. Upon arrival they were shaped with stone mauls, some of which have been recovered. Most upright stones were intentionally tapered at the apex to make them appear perfectly straight from a distance, similar to the columns of classical Greece. Surface polish was commonly applied with the pecking of quartzite hammers, although little such evidence remains today.

➤ OTHER HENGES MONUMENTS

Henge monuments are not restricted to Britain and are found throughout Ireland and continental Europe. Some of the earliest henge monuments are located on Orkney Island in northern Scotland. The famous stone circles of Stenness and Brodgar may have even provided the initial inspiration for megalithic henges in the British Isles. The large stones of Avebury are oriented in the same direction as Stonehenge, which indicates that other monuments were aligned with respect to the rising sun of the midsummer solstice. However, not all henge monuments were made of stone. Woodhenge, for instance, contained six concentric circles of postholes, which may have supported architecture. In fact, some of the largest henge monuments contain evidence of internal wooden structures, including Durrington Walls (Wiltshire), Marden (Wiltshire), and Mount Pleasant (Dorchester). Although some henge monuments contain human burials, they are relatively infrequent. At Duggleby Howe (Yorkshire) and Maes Howe (Orkney), however, earthen burial mounds are clearly present, suggesting that in a minority of cases henge monuments were essential components of mortuary practices and the expression of social ranking in prehistory.

—Noah V. Honch

The bluestones of Stonehenge weigh only a few tons and are significantly lighter than the sarsens, which weigh upward of 50 tons. Petrographic analyses identify their geological origin to be in the Preseli Mountains of southwestern Wales, more than approximately 217 miles (350 kilometers) away. Although the methods and routes of transport between Wales and the central Salisbury Plain are uncertain, a combination of water and overland travel was essential. Two routes are most likely, both of which required overland transport to the Bristol Channel and water transport along the southern coast of Wales. The shorter route involved water transport up the Severn and Bristol Avon, with a short overland haul to inland rivers leading to the vicinity of Stonehenge. The longer route involved less overland travel but necessitated transport along the unprotected waters of southwestern

England to the Hampshire Avon, which could be sailed inland to the Stonehenge environs.

Although Stonehenge may appear to be a single monument, it was constructed in multiple phases. In the first phase (Stonehenge I), the circular enclosure was constructed from the excavated fill of the external ditch. A series of holes (Aubrey Holes) were created along the interior perimeter of the enclosure that may have initially held wooden posts but were later used as repositories for cremations. The Heel Stone was placed outside of the enclosure bank in line with the northeast entrance. In the second phase (Stonehenge II), the enclosure bank entrance shifted slightly eastward, and two new stones were placed in line with the Heel Stone between newly constructed parallel banks. Bluestones were placed in an incomplete circle at the center of the enclosure but were removed sometime afterward.

The third phase saw Stonehenge as it generally exists today and represents a complex construction period that is frequently separated into a number of subphases. In brief, it was at this time that the outer circle of linteled sarsens, the central structure of large trilithons, and the transport of the distant bluestones took place. During the initial stages of this phase, a series of postholes, typically referred to as Y and Z holes, were arranged in two circles between the outer sarsens and the earthen embankment. The function of these holes is uncertain, but they may have been used to guide celebrants through the monument or create small-scale wattle-and-daub architecture.

Interpretations of Stonehenge are often shrouded by the legacy of myth and legend. Early writings attributed Stonehenge to the magical acts of Merlin, who single-handedly transported large stones between Ireland and England and arranged them according to royal decree. Renaissance thought commonly ascribed Stonehenge to the Romans, who possessed the necessary intelligence and technologies that the prehistoric Britons supposedly lacked. Other schools of thought held that seafaring Phoenicians were responsible for the movement of the sarsens, which according to belief could not have originated anywhere other than the primordial geology of Africa. Connections between

Druids and Stonehenge were not drawn until the seventeenth century and had no legitimate foundation. The explicit mention of Druids by early Roman writers in Britain, including Tacitus, Diodorus Siculus, and Pliny, made reference to religious ceremonies and sacrifice but did not ever associate them with megalithic monuments. Modern interpretations of Stonehenge are still commonly influenced by theories that were established, and sometimes convincingly refuted, hundreds of years ago.

Sweeping astronomical interpretations tend to see Stonehenge as a prehistoric computer or observatory. Most archaeologists while acknowledging the coherence of Stonehenge's orientation are hesitant to accept that prehistoric monuments functioned on the same principles as modern scientific instruments and knowledge of space. In most cases, if enough internal configurations of Stonehenge are compared to the infinite bodies of space, geometric patterns will always be found; however, it does not mean that these patterns were known to the builders of Stonehenge or were ever intended for its construction. Some clear patterns exist, however, that clearly attest to prehistoric mathematical understanding. The axial alignment of the Heel Stone and the central Alter Stone with the rising sun of the summer solstice, for instance, is virtually unmistakable. The summer solstice was an important religious as well as practical event, although such divisions may not have existed in the minds of ancient Britons. The midwinter's sunset may have been an equally important event to commemorate. Sedentary Neolithic communities were agriculturally dependent, and established calendrical systems would have been important to the timing of religious rituals and the organization of agricultural activities such as the planting or harvesting of crops. Considered in context, Stonehenge could have easily fulfilled this role for local communities. Whether it actually did, however, is unclear and will likely never be known with certainty. Thus remains the mystery of Stonehenge.

European Houses in the Copper and Bronze Age

With the arrival of farming in Europe in the Neolithic period came settled, domestic residences. Previously, people had had to move frequently throughout the year to take advantage of seasonal resources. As farming replaced hunting/gathering and foraging as the dominant subsistence practices, people built permanent homes and resided in the same locations year-round. Throughout the Copper Age and the Bronze Age in Europe, diverse styles of domestic architecture developed over the continent, contingent on locally available resources and local topography and weather patterns.

In the British Isles, houses were typically round and small. The diameter of these houses varied anywhere between 3 and 23 feet (1 and 7 meters). The size of these houses suggests that only a single nuclear family could have lived comfortably inside. Walls consisted of rings of posts or stones that probably supported a thatched roof (although roofs are not frequently preserved). Visitors to Dartmoor (in England) today can wander through fields filled with the round foundations of Bronze Age huts. Round houses dating to the Bronze Age are also found in parts of southern Italy, usually having been constructed in stone.

The most common type of house in Copper and Bronze Age Europe was the rectangular house. These houses varied considerably in size and were made mostly of wood but sometimes had stone foundations. The walls and roofs of the houses could also be made of wattle and daub, a mixture of sticks, reeds, and clay. One of the largest rectangular houses in Bronze Age Europe was found at the site of Brezno, measuring 105 by 21 feet (32 by 6.5 meters) in size. The more typical size of a house ranges from 53 to

➤ HOW ARCHAEOLOGISTS RECONSTRUCT ANCIENT EUROPEAN HOUSES

The archaeological remains of European houses are sparse. Due to the organic materials used in construction (which rot away over time) and the continuous reuse of sites over the past 6,000 years, most of the remains of houses have vanished. Archaeologists are forced to reconstruct houses based on the foundations that remain, often simply the charred remains of postholes that had been hammered into the ground centuries before. This tells archaeologists a lot about floor plans and the division of space but next to nothing about the superstructures. For that, archaeologists must rely on depictions of houses in rock art and on clay models of houses.

—Kevin M. McGeough

66 feet (16 to 20 meters) on the long side and 19 to 26 (6 to 8 meters) on the short side. These houses are significantly larger than the round houses of Britain, large enough for an extended family (or more than one nuclear family) and some livestock to dwell inside. In some cases excavators have been able to identify internal divisions of rooms. Houses recently excavated in Jutland are divided into three rooms, with internal walls (made of posts) functioning as both room dividers and roof supports.

Perhaps the most spectacular European houses that have been recovered archaeologically are lakeside sites. Houses built near or on lakes in Bronze Age Europe were well situated to take advantage of marine resources for subsistence. The houses were rectangular, but instead of being set directly into the ground, the houses were built on piles that lifted them above the water level. Piles were either placed into the lake vertically (holding up the houses as though on stilts) or were laid down horizontally (creating a platform for the house to sit on above the water). Bridges would have connected the houses, allowing people to walk through the village without going down into the water. In Switzerland, numerous waterlogged remains of these

piles were preserved when lake levels rose and covered these ancient dwellings. It seems that many of these houses were abandoned at the end of the Bronze Age, probably due to a significant rise in water level.

Less common in the Bronze Age were the so-called hilltop forts, actually fortified settlements situated on defensible hills. These types of settlements are found most frequently in Spain. The site of Cabezo de Monleón in the Ebro Valley was founded on a hill. Over 57 rectangular houses were built along the outer edges of the top hill. The houses shared long walls, and the short walls faced the outer edge of the hilltop and the interior of the village. Perhaps the best known of the Spanish hilltop sites is El Argar, which was built on a hill over 328 feet (100 meters) high. El Argar is particularly famous for the wealth of funerary remains; bodies found under the floors and within the walls of houses suggest that domestic structures were not just for the living in Bronze Age Europe.

South American Urban Planning at Real Alto

Real Alto is a village located in Ecuador associated with the Valdivia culture, which was inhabited from roughly 3300–1500 BCE. At its greatest extent, the village reached a size of 31 acres.

Throughout its occupation, Real Alto was laid out in a U-shape typical of Valdivia villages in general and common to South America. The U-shape (or ring shape as some excavators describe it) is formed by houses densely arranged

around a central plaza. Slight variations to this plan throughout Real Alto's use point to changes in social structure and political organization. In the earliest phases, the houses were roughly similar in size and quality, and the U-shape was fairly round. By around 2300, this had changed somewhat. The ring was more rectangular than circular, and two mounds with platforms on top jutted out into the center plaza. This layout lasted until about 1850 BCE and marks the period of Real Alto's largest population. Until about 1500 BCE the village remained in use, and the ceremonial mounds seemed to take on more importance than the domestic structures; the population gradually declined until it was abandoned altogether.

The earliest houses were simple wattle and daub huts. Not much of these houses survived in the material record; archaeologists identified the locations of walls by the postholes that did survive. These early houses were small one-room structures; presumably there was enough space for a single nuclear family to inhabit them. Spindle whorls and evidence of cooking have been found immediately outside of the huts in the interior plaza, so it is assumed that cooking and textile production took place immediately in front of the home. Burials have also been identified within the homes or under the walls of the homes. In the later phases of the site, the huts get larger and more rectangular, large enough for an extended family to live within.

Atop the two mounds that projected into the central plaza, two ceremonial structures have been identified. The Fiesta House contained remnants of ancient food and pottery; the excavators suggest that this may have been used for communal feasts and/or village celebrations. The Charnel House, on the other mound, yielded mostly human remains and associated grave goods.

➤ THE WANKARANI COMPLEX OF BOLIVIA

Starting around 1500 BCE, small villages began appearing around Lake Poopo. Archaeologists refer to these villages as the Wankarani Complex, named after the first site (Wankarani) where this culture was identified. The villages vary considerably in size, from 1.2 to 4.9 acres (0.5 to 2.0 hectares) in size, holding populations of anywhere from 75 to 3,900 people. Most Wankarani villages are clusters of circular houses (usually made of adobe); sometimes the entire village is surrounded by an adobe wall. In later periods, the Wankarani Complex is noteworthy for its unusual carved stone llama heads.

—Kevin M. McGeough

➤ THE SYMBOLIC LAYOUT OF MESOAMERICAN SITES

Principles of orientation in the layout of urban and ceremonial centers were systematically used in Mesoamerica. Therefore, time and space were articulated in landscape by means of the alignment of buildings and settlements to natural elements such as mountains, springs, and caves. In Mesoamerican sites, the observation of the natural environment (sky, seasonal cycles, and landscape) was instrumental in the definition of sacred geometry. Moreover, topographic devices marked the rising and setting positions of the sun or stars as landmarks of ritual calendars. Evidence from ancient codices suggests that directions along the horizon were crucial for establishing architectural structures, stressing the relationship between the cosmos and humankind.

Poverty Point in the Mississippi Valley

Arguably, the first “city” in North America is located at Poverty Point in northeastern Louisiana. Visitors to the site, now a state park, can see the remnants of the vast earthworks that, while not unusual for this region, are unusual for the time period ranging from 4000 to 1000 BCE. These earthworks are something of a mystery, as it is unclear why they were built or how they functioned. Whether or not this should actually be considered an ancient city is debatable. Some scholars suggest that this was a large settlement site. Others argue that this was a ceremonial meeting center that a human population would have used only some of the time.

The earthworks consist of six concentric ridges running in a semicircle. The ridges are broken by aisles that run straight from the outer ridges into the open central area. Each of these segments are about 82 feet (25 meters) wide. The lengths vary considerably. The ridges are about 6–10 feet (1.8–3 meters) high. They are built of earthen fill and refuse. In total, approximately 1.2 million cubic feet (35,000 cubic meters) of soil would have been needed to construct the complex. Five other mounds are associated with the complex. To the west is a large artificial mound, 22.87 yards (20 meters) high and 228.7 yards (200 meters) long. Its location appears to be related to astronomical observations. It is impossible to say with certainty what this complex was used for. Without a doubt, it reflects a tremendous amount of planning and control of labor resources.

The site itself is located on the Macon Ridge, near the Mississippi floodplain. Near the confluences of six rivers, this location was ideal for trade and transportation throughout the region. That trade took place here is likely. The material culture of Poverty Point consists of a wide variety of materials that originated throughout the eastern United States. Many scholars suggest that this was a regional exchange center. People living in nearby settlements would have come to Poverty Point to exchange locally manufactured goods for goods and raw materials from farther away.

The subsistence economy of the original inhabitants of Poverty Point seems to have been

hunting and gathering, not agriculture or horticulture. As at Stonehenge in England, the builders of the Poverty Point monuments were not participants in a complex economy. They were not settled agriculturalists, nor is there evidence for extensive craft specialization. Scholars generally assume that Poverty Point culture was organized as a chiefdom with a loose political structure organized along hereditary lines. The leaders were able to compel many people to engage in hard labor over long periods of time and commit substantial resources to the enterprise.

While Poverty Point appears to be the largest center of this culture, there are at least ten settlement clusters within the region. At least 100 sites have been identified as part of the Poverty Point culture. Each of the ten regional clusters broadly follows natural geographic boundaries, and each cluster has a central site that is larger than the others.

Domestic Structures in North America

The domestic structures of prehistoric Americans remained fairly simple and ephemeral until the middle to late Holocene period, at which point late Archaic lifeway patterns emerged. These late Archaic lifeway patterns focused on the construction of permanent architecture, the reliance on dependable subsistence resources such as domesticated floral species, and the rise of sedentary modes of existence. Prior to this period, the prehistoric people of North America constructed a range of structures for domestic activities that included pithouses, longhouses,

the use of rock shelters, and wall-trench-type structures.

For example, semisubterranean pithouses were the most distinctive form of dwelling in California for most of the Holocene. Structures typically had round floor plans in which a dome or a cone was built over a shallow pit. Pits generally ranged in diameter from 4 to 8 meters (13–26 feet) and in depth from 0.3 to 1.0 meters (1–3.3 feet). Most of these pithouses had ground-level entrances, and they typically had strong interior support posts with rafters covered by sticks, wicker, and earth to create a dome structure. Pithouses were also the common domestic structure for the Plateau and parts of the Great Basin and Southwest regions. Because of the time and effort required to construct pithouses, they generally are only found where resources were rich enough to make recurrent seasonal occupation possible. The earliest pithouses are located in northeastern California and the Plateau region, where they date to 5,500 years before the present. In the Southwest and Great Basin, the earliest known examples of this form of domestic structure use dates to 2000 BCE.

Another form of domestic structure used in North America during the middle and late Holocene periods is that of the longhouse, also called a plank house. Longhouses were pole framework structures covered by long woven mats of bark, cedar planks, or other materials and were often 18–30 meters (59–98 feet) long, although evidence indicates that some were longer. Longhouses were common along the northwestern coast and in parts of the Plateau region where the abundance of trees for use in constructing the structures were common, with the earliest known dating to around 1000 BCE. For example, evidence from southern British Columbia indicates that people lived in villages made up of big rectangular, heavy-timbered structures arranged along the shore in rows. On the coast of Washington, the Ozette site contains perhaps the best preserved of these longhouse structures, although it is not the earliest known example. Nearly 20,000 structural members have been recovered, including roof, wall, bench, and drain planks; rafter support posts; and support poles for walls, benches, and drains. At least three of the houses found at the site contained drainage-

Pipe Shrine House, a pithouse at Mesa Verde National Park in southwestern Colorado. (Caitlyn Willows)

control trenches to divert ground runoff from the longhouse roofs.

In the Great Basin and other regions where resources were not as abundant to use for the construction of domestic structures, people used rock shelters or ephemeral brush and twig structures as their domestic residence. Throughout the Great Basin and in parts of the Southwest people used rock shelters as a primary domestic residence, usually modifying the living floor and in some cases creating walls or wind blinds by stacking rocks at the rock shelter mouth. Temporary structures were used for forays away from the centralized rock shelter, which were generally constructed of locally available resources such as reeds, sticks, and branches in the form of a small dome shelter. Evidence of rock shelters being used as a domestic structure has also been recovered for parts of eastern North America, although it appears that these were not the primary place of domestic residence for the people of the region.

Beginning in the middle Holocene period and continuing through the late Holocene period, people of the Southwest region also used adobe to construct various domestic structures. Adobe is a sun-dried brick made of clay, vegetable fiber, and water. The adobe bricks were used by people in the Southwest to make what are called pueblos, which are substantial above-ground structures that have contiguous rectangular rooms.

Contrary to these forms of domestic structures, in the Midwest the use of wall-trench

THE BAILEY SITE

The Bailey site located in Giles County, Tennessee, provides evidence of both summer and winter Middle Archaic domestic structures. Dating between 3750 and 3200 BCE, the site contains evidence for a total of five structures as well as several storage pits and hearths. Three open rectangular structures measuring 4.4 by 7.7 yards (4 by 7 meters) long and 2.8 by 4.5 yards (2.6 by 4.1 meters) wide containing interior hearths and shallow to medium pits have been interpreted as single-family warm-weather shelters that are thought to have been used during summer months. The other two structures, thought to be winter houses, are fully enclosed structures measuring 9.7 by 11.5 yards (8.9 by 10.5 meters) with two internal hearths and nine large pits. Evidence indicates that these pits were used for winter storage of a diverse array of floral and faunal resources. The walls of these larger winter houses were most likely made of wattle and daub construction, while the frame was made of large posts. Because both summer and winter domestic structures were found at this site, it has been concluded that the Bailey site represents a Middle Archaic year-round habitation site.

—Peter N. Jones

structures was common and is often associated with the Mississippian tradition (1050–350 years before the present), although its use has been found outside the Mississippian area. Long, narrow trenches were dug around 25–40 centimeters (10–16 inches) deep, and small posts were set within them to form relatively substantial walls and interior partitions. Most wall-trench structures were square or rectangular semisubterranean buildings that had a wattle-and-daub sheathing covering the walls and thatch to cover

the roofs. The remains of interior benches, floor supports, fireplaces, processing racks, storage pits, and other features are often found in the structures. Evidence indicates that wall-trench structures were usually components of spatially distinct household clusters that consisted of a grouping of one or two wall-trench structures, storage and processing pits, and other specialized features. The other common domestic structure in eastern North America was that of the wigwam. Wigwams were lightly built structures, usually made of branches and other materials, in a variety of shapes and sizes, although heavily built single-post examples are also known.

Introduction: Art

Artwork is one of the great contributions made to world culture in this period. Throughout the time from 4000 to 1000

BCE, art displays a high level of technical sophistication, aesthetics, and multiplicity of styles and techniques. The ability to manufacture complex

designs in a number of media, in metallurgy especially, developed beyond the rudimentary levels.

Art can be found in many forms throughout the age, but most scholars think of art as sculpture, painting, or the combination of the two (such as inscribed wall reliefs or painted statues). One of the problems in studying these ages is that often the artistic pieces that have been recovered from an archaeological site are not fully preserved. Many Egyptian and Mesopotamian statues were sculpted so as to wear clothes, jewelry, or other adornments that do not survive as well in the archaeological record. Frescoes are usually not preserved directly on walls; frequently they have fallen face down into the room of the building, and archaeologists must carefully lift these paintings up and reconstruct their original provenance. In the case of the Minoan palace at Knossos, these reconstructions were made based more on the imagination of the excavators than on any rigorous scientific basis. A further danger to the study of ancient art can be the museum conservator. If a conservator is too aggressive in restoring a broken piece of ancient art, then sometimes the conservator's artistic sensibility can overwhelm the original artist's creativity. The rule of thumb when studying ancient artifacts is to first identify what is original to the piece and what has been added by later conservators.

More problematic than issues of recovery and preservation is the fact that we no longer share the visual culture of these ancient artists. Some of the art fits nicely into our modern conception of art. The Shang bronzes are unanimously taken as objects of incredible beauty and sophistication. Modern viewers are readily drawn to Egyptian art, with its fine proportion and balance, so much so that ancient Egyptian aesthetics are often used as the basis for more recent artistic styles, art deco being the most notable example of this. Yet Mesopotamian art is often described as strange, alien, and lacking in aesthetic refinement. When studying ancient art in order to understand the past (a different enterprise than attempting to understand the development of art), one must try to understand the art from the worldview of the ancients. Art involves shared conventions (even when an artist

breaks with convention, there is still an acknowledgment that those conventions exist), and to understand ancient art, one must try to reconstruct what those conventions were. For example, students often comment that the posture of humans in Egyptian art looks somewhat awkward, since faces are almost always depicted in profile, yet the body is twisted to face straight ahead toward the viewer. This does not reflect a lack of skill in portraying bodies and movement in ancient Egypt; rather, it reflects very strict conventions of how the human body was supposed to be depicted.

The Rock Art of the Tassili n' Ajjer

Located approximately 932 miles (1,500 kilometers) from the Mediterranean Coast in the central Sahara in Algeria, the Tassili n' Ajjer is home to fantastic ancient African rock art. Over 15,000 drawings and engravings have been identified, most of which probably date to the period between 1000 BCE and 300 CE. This region was once lush and fertile, not the barren desert that visitors can travel through today. In ancient times the region would have been spectacular, with unusual rock formations jutting out of the ground, some monumental in proportion. Nestled among these rock outcroppings are shallow caves and steep cliffs, now breaking up the surrounding sand flats, described by UNESCO as "forests of rock." The geological beauty is enhanced by the unique rock art found throughout.

This rock art was discovered by Europeans in 1909, by a French military officer. Until the 1930s, a series of French military expeditions explored the region, occasionally mapping the paintings. In the 1950s, Swiss explorers traveled through and took note of the remains of ancient Africans. Formal scientific work began in the early 1960s with a French expedition led by Henri Lhote. Much of the formal artistic analysis of the Tassili n' Ajjer rock art has been based on the initial interpretative work of J. D. Lajoux. The general working hypothesis that has arisen from this research is that the art can be divided into four general stages. The earliest stage, dating to sometime before 4500 BCE, is referred to as the

► THE EGYPTIAN HOAX

On an archaeological excavation, the temptation to play practical jokes can be almost impossible to resist. In the case of the Lhote expeditions, a practical joke went too far, making its way into many of the published reports and into the scholarship on the Tassili n' Ajjer. Some members of the expedition chose to paint their own rock art, creating humans standing in ancient Egyptian postures and wearing ancient Egyptian head-dresses. Two of these modern paintings were included in Lhote's monograph on the subject in which he argues vehemently that the Tassili n' Ajjer art was influenced by Egyptian art. While these forgeries have been removed from subsequent editions of the book, scholars still discuss the so-called Egyptian influences on Saharan rock art, not realizing that the Egyptian influence is entirely modern.

—Kevin M. McGeough

White Figure period or the Archaic stage. Following this is the Bovidian Tradition, which is associated with the domestication of cattle in the region, probably around the beginning of this period. After that are two successive stages: first, the Horse Stage, and second, the Camel Stage. Unlike rock art in other regions, there are no associated artifacts in cave deposits that could provide stratigraphic dating information or radiocarbon dates. Given the current state of knowledge on chronology (which is not expected to change any time soon), these dates and stages must be considered very hypothetical.

The rock art consists mostly of paintings or drawings (the distinction is difficult to make when it comes to rock art), although some are engraved or partially engraved. The paint was made of locally available materials (especially ochre) that were ground up into a powder and mixed with a solvent. At least some of the images were applied with a brush, and all were done directly on the stone. Some may have been traced lightly beforehand; the evidence is ambiguous. Styles vary considerably, but some broad generalizations can be made. Usually there is no groundline (although sometimes part of the natural rock stands in for this), and the individuals

are oriented chaotically upon the stone face. Scale and size vary dramatically within individual compositions. It is difficult to be certain which figures go with which and if there is any narrative conveyed by the art. Often figures are superimposed upon other figures.

The chronological schema mentioned above is roughly based on the subjects of the artists (and more loosely based on identifiable stylistic conventions). The subjects of the so-called Archaic Art are masks, human figures wearing masks, individual body parts (mostly arms and genitalia), and abstract symbols. With the advent of the Bovidian period, animals and humans become the most frequently attested figures. There are some ostriches and some fish but many land mammals. Of most interest are the images of cattle (hence the name "Bovidian"), which are depicted in unparalleled detail. It is possible to identify individual species of cattle since the depictions are of such high quality. In the final stage, geometric shapes are very frequent.

The art of the Tassili n' Ajjer provides historians with information on many aspects of daily life in North Africa. The clothing on the human figures gives us some hint as to what ancient African clothing would have looked like. Humans are depicted using a number of tools, including pottery, bows, arrows, spears, clubs, and drills. Various activities are attested as well. Most important is evidence for cattle pastoralism; collars on cattle and cattle in pens are all apparent in the artwork, demonstrating that these North Africans did, in fact, engage in these practices. Some horticulture may be in evidence; scenes of individuals drilling with bows look much like modern horticultural practices in North Africa. These same images could also be understood as depictions of fire production or drilling for water. From this art, we also know that hunting was important.

The function of this art in antiquity is poorly understood. Most scholars do not believe that this was merely art for art's sake, although there is no evidence (beyond modern biases in taste) to prove that aesthetics did not play an important role in its production. Scholars postulate a number of possible functions. These paintings may be commemorative, may indicate places where important events occurred, mark holy sites, or

distinguish group boundaries. Some scholars suggest that these may have played an apotropaic role, that is, they had magical powers to influence real-world events, probably providing fertility or safety for the community. Whatever the case may have been, the Tassili n' Ajjer is now a UNESCO world heritage site, a designation that recognizes its importance in human history.

Ancient Egyptian Art

Ancient Egyptian art has a very unique flavor that makes it easily recognizable by most viewers. However, a real appreciation of the art of the ancient Egyptians cannot be reached without a good understanding of the culture of the people who produced it. The art of the ancient Egyptians was mainly functional in purpose. Its main concern was to ensure the continuity of the universe. The ancient Egyptians were firm believers in life after death and spent considerable amounts of time and energy trying to ensure that their next lives would be idealized versions of the lives they had lived on earth. Therefore, most artistic representations did not focus on achieving realism as much as on producing idealized forms that would last for eternity. The ancient Egyptians believed that what was represented through art became, in a sense, real. For instance, a statue carved by a sculptor to represent a particular deity actually became that deity. Offerings were presented to it, and it was carried around in procession during festivals.

It is important to point out that the ancient Egyptians had no term for “art.” Their vocabulary included words for specific monuments such as “tomb,” “stele,” “statue,” etc. The artists who produced these works of art were usually anonymous. Unlike modern art, which is highly individualistic, the ancient Egyptian artist was a

conformist. Artists had to abide by a strict set of rules. This is why ancient Egyptian art appears, to the untrained eye, to be very static. This, however, is not entirely true. Since ancient Egyptian art was closely tied to the view that the artists had of the world, it only changed when there was a change in this view. The most obvious example of such a change took place during the reign of the so-called heretic king Akhenaten (1352–1336 BCE), who is also known as the world’s first monotheist. The art of this period (known as the Amarna period), especially the royal art, was very distinct from the highly idealized forms produced in other periods of ancient Egyptian history. Images of the king were characterized by a large head, a long neck, narrow shoulders and waist, and a high small of the back, making the upper torso appear small. The lower body is characterized by large buttocks and thighs, giving the king an effeminate appearance. The arms and lower legs were thin and lacking in musculature. These characteristics were not restricted to images of the king but were typical of all representations of human figures of the period.

Art of the Amarna period is different from that of all other periods of ancient Egyptian history in that it broke many of the rigid rules that governed ancient Egyptian art production. It still obeyed certain rules, such as the rule of frontality in sculpture (i.e., the idea that most large-scale statues were designed to be viewed from the front, since they were intended as architectural components), and rules governing two-dimensional representations of the human figure, such as depicting the head in profile, with the eye and eyebrow shown fully frontal, the shoulders shown fully frontal, while the waist, limbs, buttocks, and breasts are shown in profile with a full view of clothing and jewelry. The art of that period, however, broke important rules of proportion as well as the idea that royal figures should be represented as idealized demigods. Scholars differ in their interpretation of the possible reasons behind this artistic revolution.

Finally, it is important to point out that the ancient Egyptians did not distinguish between arts and crafts. Books on ancient Egyptian art usually contain such items as furniture, coffins, toys, and jewelry. Art for art’s sake was very rare;

➤ BUST OF NEFERTITI

In 1912, during the excavations of the Deutsche Orient Gesellschaft of Akhenaten's capital city Akhetaten (present-day Tel el-Amarna) led by Ludwig Borchardt, a beautiful painted limestone bust was found in the deserted workshop of the sculptor Thutmose. It was found among about two dozen pieces, the majority of which were heads but also included busts and complete statues, almost all were

unfinished. The bust was that of a very beautiful woman, recognized by her flat-topped crown as Akhenaten's chief wife, Queen Nefertiti. This bust is a testimony to the fact that ancient Egyptian sculptors were capable of producing realistic, delicately carved portraits that boasted the high craftsmanship and sensitivity of the artist. This beautiful portrait of the queen is very different from the distorted two-dimensional representations that resembled those of her husband. It suggests that the Amarna distortions of figures of members of the royal family were the result of a certain ideology rather than reflections of reality. Unfortunately, the face of the queen is missing its left eye. The reason why the left eye was never finished is unknown. Nevertheless, this infamous bust has remained an icon of beauty through the ages. The bust is now in the Ägyptisches Museum in Berlin.

—Yasmin El Shazly

Bust of Nefertiti, fourteenth-century-BCE Egyptian queen and wife of Pharaoh Akhenaten. (Jean-Pierre Lescourret/Corbis)

it did nevertheless exist and was particularly visible in the village that housed the workmen who worked on the royal tombs of the Valley of the Kings, between the Eighteenth Dynasty and the later Ramesside period (ca. 1550–1069 BCE) known today as Deir el-Medina. Large numbers of chips of limestone and ostraca (broken pieces

of pottery) were found on which the workmen drew sketches, many of which seem to have been done for pure entertainment; for instance, they drew caricatures mocking their overseers and images that clearly broke the artistic rules of the time. It is possible that the shortage of examples of works of art produced for art's sake was due to a lack in the archaeological record of sites such as Deir el-Medina, which provide information on the everyday lives of the ancient Egyptians.

Syro-Palestinian Artwork

Far less art has been discovered in Syria-Palestine than in the neighboring regions of Egypt and Mesopotamia. Artistic production in the southern Levant involved significant interaction with artistic forms from both of these neighboring regions, as well as, in some cases, with the Greek world. The adaptation and reinterpretation of foreign styles according to local traditions made Levantine art relatively unique.

Significant advances in craftsmanship are apparent in the Chalcolithic period, most notably in the Nahal Mishmar Hoard of weapons. Art that originated outside of a warfare context is also well attested. Several forms of small statuary and figurines were used during the Chalcolithic period. These include anthropomorphic and animal figurines made of ceramic and stone. Violin-shaped figurines have been found at a number of Levantine sites, especially Gilat, which had more than sixty examples made from a variety of materials. Some are clearly female, as certain examples have breasts. A corpus of small ivory figurines from sites in the Beer Sheva area probably dates to later in the period. These figurines include representations of both sexes and are indicated by detailed genitalia. There are also

stone-carved heads, sometimes referred to as “Pinocchio figurines,” the schematic style of which, particularly their pronounced noses, link them to the ivory tradition. One unique bone figurine from Shiqmim shares elements of both the earlier violin-shaped tradition and the Beer Sheva ivories.

Two outstanding ceramic sculptures from this period both come from Gilat, including the “Lady of Gilat” and the “Ram with Cornets.” The former is a representation of a female figure sitting on what may be a birthing stool and holding a churn on her head, while the latter is a ram with three cornets protruding from its back. As both were found in a cultic context, and both concern aspects of pastoral production, they have been interpreted as relating to ritual beliefs concerning fertility. A ceramic figure of a bull similar in style to these has been found at Ein Gedi.

Art from the Early Bronze Age demonstrates close connections between the southern Levant and Egypt during this period. The various types of glyptic art that appear in the Early Bronze Age, especially seal impressions, form an important part of the material culture of the period. The stamps and cylinder seals themselves that were used to make these impressions have not been found, however, as many may have been made from wood. Seal impressions from Egypt or Egyptian-style stamp seals have been found throughout southern Canaan at sites such as Halif Terrace, Arad, and En Besor.

Seal impressions from cylinder seals are known from a number of northern sites, including Beit Yerah, Dan, Hazor, Megiddo, and Tel Qashish. Typical geometric designs include spiral, herringbone, and lattice patterns, which suggest a connection with Asia Minor or perhaps the Aegean. Seals from Jawa, in the semiarid region east of the Jordan Valley, show a Syrian influence, while a Byblite and Mesopotamian (Jemdet Nasr) influence is evident in many seals. Figurative designs involving lions and horned animals were also used, many forming schematic motifs, as seen in seals from Megiddo and Jericho.

Pictographic art also appears in the form of engraved images found in stone and on pottery. At Megiddo, horned animals were incised on the stones used to pave the cultic area, and at Arad the Dumuzi Stele depicts human stick figures.

Serekhs, essentially the insignias of Egyptian kings that ruled at the end of the fourth millennium BCE, were incised on the bodies of vessels, often wine jars. The symbols of several different rulers (for example, Narmer and Hor-Aha) were also found on sherds from a number of Levantine sites, including Ai, Arad, Azor, Halif Terrace, and Tel Malhata.

Gold continued to be quite rare during the Early Bronze Age. There are beads made of gold, and a gold disk, possibly from Asia Minor, found in a burial cave near Beit Yerah. Silver, even more rare and more valued than gold at the time, was also used to make beads, and one of the most outstanding singular artifacts from this period is the silver bowl from Tel el-Farah North. Ivory was used to make various items, notably bulls' heads, which have been found at Beit Yerah, Jericho, and Ai in Early Bronze Age (specifically EB3) contexts, all of which display a remarkable similarity in style. Carved bone handles with geometric designs (for example, spirals and herringbone patterns) similar to those appearing on seals have also been found at these sites, bolstering the possible connection with Asia Minor.

Expensive luxury goods are actually quite rare during the Intermediate Bronze Age. One exception is the silver vessel from Ain Samiya. This piece displays expert craftsmanship with the use of the repoussé technique and was decorated with various mythical beings, pointing to a Syrian origin. Items of personal adornment were sometimes made of copper during the Intermediate Bronze Age. Toggle pins of various types appear, including short, simple types as well as longer examples that sometimes have eyelets or knobbed heads. The latter are similar to contemporary pins from northern cities such as Byblos and Ugarit. Earrings, bracelets, and rings made of copper also appear, usually as burial goods, during the Intermediate Bronze Age.

Imported goods from Egypt and Syria are also typical of Middle Bronze Age assemblages, attesting to the networks of international trade that began to emerge during the period. Scarabs bearing royal Hyksos names written in Egyptian hieroglyphics have been recovered at Tel el-Ajjul (City 2). In some cases, the scarabs appear to use the Egyptian symbols in a somewhat random

fashion, and at times the glyphs are replaced altogether with geometric shapes. Syrian cylinder seals have also been found at Canaanite cities, mostly in the north.

A particular style of glyptic art called the “Syrian Style,” which combines Mesopotamian, Egyptian, and local motifs, emerged during the eighteenth century BCE. This syncretistic genre ultimately spawned a number of motifs that are now regarded as uniquely Canaanite, in particular those portraying the deities Hadaad-Baal and Astarte. Mythical beasts such as the griffin and sphinx, native to neighboring lands, were spun into local Canaanite versions, while random symbols such as the ankh were used to fill space. Human (or divine) figures are also depicted in many seals. These figures sport the styles of the Canaanite noble class, such as the long robe and beard for men.

One other medium where Canaanite artistic and iconographic styles can be observed is in the small plaques made of bone used as insets to decorate wooden items such as jewelry boxes or furniture. These inlays employ a range of motifs, including naturalistic figures such as birds, lions, cattle, and various other animals, in addition to humans; the men depicted often have an Egyptian “attitude,” as do some of the birds, and a symbol that closely resembles the Egyptian Djed column was also used. There are also inlay pieces in the form of strips that may have been used as border trim. These feature a range of geometric designs, including rows of concentric circles, zig-zag triangles, and other symbols.

The glyptic art of the Late Bronze Age reflects various foreign influences, including seals in the Mitanni style depicting lions, winged beasts, griffins, and horned animals. Other seals show a Cypriote-Aegean influence, while Assyrian motifs begin to creep in. It is also during this time that Proto-Canaanite and Proto-Sinaitic inscriptions begin to appear. In some instances, such as the celebrated “Charioteer Vase” from Tel Dan, elaborate images were painted onto fancy vessels.

Artistic styles can also be seen in the sculptures that were sometimes incorporated into the architecture of temples and palaces. Lions depicted in sculptural work at Hazor and Beth Shean have parallels with Syria-Cilicia, especially the city of Alalakh. Several unique examples of

Canaanite sculptural art of the Late Bronze Age come from the Hazor shrine (Area C), including a group of small stelae, a statue of a seated male figure, and a small, sculpted lion. Artifacts made of carved ivory were also used, with several outstanding examples from Megiddo, including a long piece of inlay that may be from a knife handle, a pyxis with lions and winged beasts, and a plaque crowded by figures both mythical and naturalistic. Although the latter shows a Syria-Cilician influence, other ivory pieces are more Aegean in style.

Greek Art—From the Neolithic to the Iron Age

The dawn of artistic production in Greece dates back to the Neolithic period, approximately the sixth millennium BCE. The first true Greek art, art that can be associated with a people who definitely spoke Greek, only properly begins with the Mycenaean culture of the sixteenth century BCE. Numerous important trends developed in the arts in Greece from the Neolithic period continuing through the end of the Mycenaean period and the beginning of the Iron Age.

The artist in these early periods of human history was not so much an artist as an artisan. Any discussion of the art of the Neolithic period and the Bronze Age for the most part describes the production and decoration of pottery vessels, ceramic figurines, and small stone sculptures. Although this may not look like what we call art

today, each object displays artistic choices made by their creator. Vessels were utilitarian, but they were also carefully decorated. Artists chose specific and meaningful modes and motifs for representation.

In the Neolithic period in Greece and on the Greek islands there is a wide interest in depicting the human form. Many small clay figurines depicting men and women and often emphasizing the breasts and hips of women have been found. These figurines are often taken to be an allusion to women's fertility and carry important social or ritual connotations. These are the precursors to more developed sculpture. The pottery, too, shows aesthetic considerations. It is decorated with thoughtful linear and geometric designs that harmonize and enhance the shapes of the vessels themselves.

By the Early Helladic period, the third millennium BCE, two major innovations shaped artistic production in Greece. The first was the introduction of the fast potters' wheel. The fast wheel allowed the potter to create more elegant and graceful vessel shapes so that the need for vase painting actually declined. The second innovation was the mastery of metalworking techniques. Beautifully crafted pieces of jewelry, vases, tools, and weapons are the hallmark of the Early Helladic period. The metalworking of the period shows considerable influences from Anatolia and the eastern Aegean from which the metals technology probably reached Greece. The Early Helladic period is also known for a development in art that took place in the Cycladic islands off of the Greek mainland. Here a particular type of stone sculpture developed from earlier more abstract Neolithic examples. The white marble sculptures are of both males and females and range in size from about 6 inches to 15 inches. They often show the figures lying down with arms crossed over their chests. A few examples show figures playing musical instruments. These sculptures show a development in the study and rendering of the human body in stone that was not to be achieved again in Greece until the Iron Age.

In the next period, called the Middle Helladic period, Greece was experiencing a transitional period or even a downturn. The cultural arts stagnated during this period, although this

➤ MYCENAE—THE SHAFT GRAVES

With one important discovery, Heinrich Schliemann opened the doors to the Mycenaean Age and what he believed to have been the world of Homer. In 1876 in his excavations at Mycenae, Schliemann found two circular graveyards lying just outside the older city. Carved stone stelae marked some of the graves. Their contents were astonishing. Schliemann found gold and silver death masks, exquisite weapons, jewelry, and vessels of precious metals and stones. Beautifully carved daggers and cups and the gold jewelry found in the Shaft Graves showed a heavy dependence on the rich culture of Minoan Crete. Other materials such as amber, ivory, and gold showed that Greece also had contacts with Europe, Egypt, and Syria. The earliest burials can be approximately dated to circa 1600 BCE. Here lay the early kings and royal family of Mycenae. This massive accumulation of wealth and the apparent emergence of kingship in Greece marks for archaeologists and historians the beginning of the Mycenaean Age.

—Susan Helft

may be the time when Greek speakers first migrated into their eventual homeland. It was in the next period, called the Late Helladic period (also known as the Mycenaean Age), that there was a flowering of artistic production and that the foundations for later Greek art were formulated. This flowering can be pinpointed to a particular moment and place in Greek history, the period of the Shaft Graves at Mycenae. In the extraordinarily wealthy tombs of Mycenae's elite, the characteristic forms of Mycenaean art emerged. The main feature of Mycenaean art was that it borrowed heavily from its neighbor Crete, where the more advanced Minoan civilization flourished. It was from Crete that Mycenaean craftsmen learned the more complicated techniques of metalworking and jewelry making. Several features, however, distinguish the Mycenaean products from their Minoan counterparts. Minoan art is almost entirely focused on naturalistic renditions of nature, with peaceful subjects and free-flowing compositions. In contrast, Mycenaean art often focuses on military

subjects and maintains strict symmetry and austerity in its decorative elements.

Examples of Mycenaean art range from wall paintings, exquisitely painted pottery, sealstones, ivories, and metalwork. By the thirteenth century BCE, Mycenaean vases were prized throughout the Mediterranean for their quality of manufacture, the variety of their shapes, and their painted decorations. Toward the end of this period Mycenaean vase painting became increasingly pictorial and focused on representing scenes of warriors and fighters, human activity, and animals and birds. Some of these scenes presage the figural scenes on Greek geometric pottery and the full-blown pictorial pottery of the Archaic and Classical stages of Greek art.

In wall painting, the Greeks did not stand out; their compositions were clumsy and primitive compared to their Minoan counterparts. Nevertheless, the characteristic Mycenaean interest in conflict is best demonstrated in this format, as can be seen in the battle scenes of the Palace at Pylos. Perhaps the most beautiful of Mycenaean art is found in their ivory carvings and on seal stones. Here the Mycenaean craftsmen had a delicate hand and a naturalistic eye. In ivory sculpture the carver showed an interest in and knowledge of human anatomy and mastered the rendering of movement and garments. A similar mastery in representing motion and volume can be found on engraved seals, many of them considered masterpieces of Mycenaean art.

The Art of the Indus Valley

The fine arts are surprisingly poorly represented in the Indus civilization, with only a few known sculptures in bronze and stone; these, however, include some pieces of the highest aesthetic standard. Lively figurines of people and animals, in terra-cotta and other media, attest to Harappan participation in a long-lived and vigorous

The "Priest-king" sculpture of Mohenjo-daro. (J. M. Kenoyer, Courtesy Dept. of Archaeology and Museums, Government of Pakistan)

folk art tradition. Almost every creature in the Harappans' world, from fishes and hares to elephants and rhinoceroses, were depicted as figurines or as images on seals and other objects. Pottery painted with both representational and geometric designs also continued earlier traditions. There may have been painted designs on other media such as walls and wall hangings and woven patterns in textiles. The artistic abilities of the Indus people are reflected best in the superb images on their seals.

Of the very few Harappan stone sculptures, almost all come from Mohenjo-daro. Some are unfinished, and most are broken, possibly deliberately. (An attractive though quite untestable hypothesis suggests that the human figures represent a line of kings who were overthrown and their portraits smashed.) They are all quite small:

the famous Priest-king torso, for example, is only 6.8 inches (17.5 centimeters) high.

One poorly preserved head may depict a woman; all the rest are male. These generally wear a robe, draped to expose the chest and right shoulder, over a garment resembling the modern dhoti. They are normally sitting on one leg with the other knee raised and clasped by the corresponding arm, perhaps in reverence or supplication before a deity. They have almond eyes and parallel lines representing a beard, though some may be clean shaven. Braided or wavy lines depict the hair, often tied in a bun and held in place by a fillet. The finest example, known as the Priest-king, is a calm, austere figure with short, neatly combed hair tied in a headband with trailing ribbons. The angled flat back to his head suggests that a headdress was formerly fixed here. His robe is decorated with trefoils, originally filled with red paste. The sculptures vary in quality, and their features and expressions are all different, suggesting that they represent real individuals.

Two small sculptures from Harappa are carved in an extremely naturalistic style very different in feel to other Harappan figures. Each is a naked male torso; while the legs of both have broken off, dowel holes show that the arms and head were separately attached. One seems to be dancing, his upper body swinging to one side and his left leg raised in the opposite direction. The other figure also appears to be moving. John Marshall compared the dancing figure to later images of Shiva Nataraja (Lord of the Dance).

There are also a few animal sculptures, including a beautiful stone ram. In contrast, an incomplete composite beast, a bull with an elephant's trunk and ram's horns, is heavy and lifeless.

Marshall suggested that some objects represent the classic Indian male and female symbols, the *lingam* (phallus) and *yonī* (vulva or womb), associated in more recent times with the worship of Shiva. Certainly a few stone cylinders are unmistakably phallic. Several hemispherical stone stands, including a finely polished example decorated with trefoils, had a central hollow that must have held an upright stone or wooden post, plausibly creating a combination of *yonī* and *lingam*, a common symbol in later Hindu

art. A complete example of this combination in terra-cotta is known from Kalibangan.

Bronzes are even rarer than stone sculptures. These demonstrate the Harappans' mastery of complex *cire perdue* casting. The most famous is the charming figure from Mohenjo-daro known as the Dancing Girl, an extremely thin, unnaturally tall young woman with her hair in a bun and clad only in an armful of bangles and a small necklace. Her left hand holds something, while her right hand rests on her hip, and she stands in a relaxed pose very true to life. Another, compositionally similar, figure is far less convincing: she stands stiff-legged with none of the insouciance of the Dancing Girl; Shereen Ratnagar has humorously dubbed her "the ugly sister." An incomplete bronze from Chanhudaro probably depicts a man throwing something overarm or dancing with a raised arm. In addition, two miniature bronze animals are known from Mohenjo-daro: an exquisite naturalistic model of a water buffalo tossing its head and a lively goat forming the end of a pin.

The charming Harappan terra-cottas are very different from the sculptures. They are often quite crudely modeled, with tubular arms, pinched-out noses, and clay blobs and strips attached to represent everything from eyes and mouths to headgear, jewelry, or the markings on animals, but they are brimming with vitality. Some of the animal figurines are of a higher standard, very carefully modeled with attention to detail and quite true to life.

Some terra-cottas are models from the real world: posed women standing in their finery; seated men or unadorned women engaged in everyday tasks; carts loaded with miniature pots complete with driver and team of draft bullocks, among the most delightful of Harappan products; and a host of animals, particularly bulls but also pets, domestic animals, birds, and wild creatures. A charming figurine from Harappa shows a dog in a decorated collar on its hind legs begging. Some were probably toys: wheeled carts and animals with wheels or jointed to allow their heads to bob or their limbs to move. While human figurines are often scantily clad, great attention was paid to details of their often elaborate hairstyles, headdresses, and jewelry. Many female figures wear their hair folded up over a

THE ARTISTRY OF THE ARTISAN

Some fine pottery vessels were painted with designs in black on a red-slipped background. In the earlier part of the Indus period, the designs often included plant and occasionally animal motifs, such as peacocks or pipal leaves, as well as geometric patterns, but later painted wares usually bore only the latter. These included designs using intersecting circles, a distinctive fish-scale pattern, and hatched squares or triangles.

The Harappans must have also created art in perishable media, such as textiles of cotton and possibly flax and Indian silk. The exuberant geometric decoration on pottery may reflect textile designs. Shell and ivory inlay pieces were used to decorate wooden furniture. The Harappans probably used wood for many other objects, including figurines, with carved or painted decoration.

Jewelry also reflected Harappan artistic sensibilities. The finest goldwork employed skilled techniques such as granulation and filigree work, and gold and silver were beaten into paper-thin sheets or drawn into fine wire. Beads were particularly popular. Technical mastery of the bead maker's craft was shown in the production of exceptionally long carnelian beads, each taking as much as two weeks to make, and minute steatite beads less than .04 of an inch (1 millimeter) in diameter. Highly prized patterned stones such as banded agate were worked so as to expose bands encircling the bead or a series of circles or eye patterns of concentric circles over its surface.

—Jane R. McIntosh

pannier or fan-shaped frame or piled high on their heads; others have a simpler bun or turban. Some wear a short skirt and sometimes a substantial bead belt. Their jewelry includes ear ornaments, pendants, and anklets. Many have neck chokers with pendant beads and bead necklaces of graduated lengths virtually covering their chests. The less common male figurines are generally naked, though some wear a turban; the majority are bearded, and they rarely wear jewelry.

Other figurines are caricatures of reality or perhaps characters from folktales. These include figures with animal heads and vaguely human

pot-bellied bodies. One delightful example has a trumpet for a nose and is covering its face with both arms.

It is on the tiny steatite seals that Harappan artistic skill is best displayed. Some show schematic scenes, peopled with stick figures; in other scenes, however, the figures are lively and perfectly proportioned, their features completely naturalistic and the composition well balanced. Most seals are decorated with a single animal. Although only a few centimeters long, these are miniature masterpieces, beautifully observed portraits of animals true not only to the anatomical detail but also to the spirit of the beasts.

The most common image was a unicorn with features of both bull and antelope. This is the most subtle version of the composite beast theme: some of the other hybrid animals are grotesque. Occasionally figures combine features of people and animals, particularly bulls, buffaloes, and tigers.

Although narrative scenes appear on seals, they are more commonly found on small incised steatite or mold-made terra-cotta or faience tablets, found mainly at Harappa but also at Mohenjo-daro. They are often interpreted as amulets, as are tiny animals molded in faience or carved in shell or ivory. Carefully modeled and realistic, these include creatures not known from the terra-cottas, such as fishes, monkeys, hares, and squirrels. Among the wide range of other ivory objects are beautiful gaming counters, thin rectangular rods with tops fashioned as ducks or other birds or animals.

Artistic Motifs from Egypt to India: Connections and Comparisons

Toward the end of the fourth millennium BCE there is a remarkable shift in the organization of society in Mesopotamia. Scholars call this the urban revolution, the shift from small rural settlements and economies to the hustle and bustle of city life. The transformation that took place in Mesopotamia was followed soon thereafter by and probably contributed to the rise of urban centers to its west and east from Egypt and Syria to Iran and the Indus Valley. In this period, the Early Bronze Age, study is focused primarily on the three urban cultures that grew up around fertile river valleys. These are Sumer (roughly the location of present-day Iraq), Egypt, and the Indus Valley or Harappan civilization in present-day India and Pakistan. It is certain that these civilizations were in contact with one another at least by the middle of the third millennium BCE. Sumerian texts from the third millennium mention place-names as far away as Oman, India, and the Gulf states, and traces of these contacts can be recognized in the shared artistic motifs and styles found at these sites.

Of the Early Bronze Age Near Eastern world, Egypt was the most isolated. Little influence from Egypt can be seen in Sumerian culture, although early Mesopotamian influence on Egyptian culture is apparent, so much so that early Egyptologists claimed that pharaonic Egypt was founded by eastern invaders from Sumer and Iran. While such a conclusion is drastic and unwarranted, certain features of Egyptian civilization do indeed imitate Mesopotamian motifs and practices. It is certain that the Egyptians learned from the Sumerians how to seal jars and doors using a cylindrical seal. In fact, a few Mesopotamian cylinder seals have been found at Egyptian sites. Certain iconographic motifs on Egyptian predynastic artifacts imitate images found on Mesopotamian seals and sealings from the late fourth millennium BCE. These include the images of a man dominating two lions and of animals with long intertwined necks. In Egypt these

images adorn luxury items such as cosmetic palettes (e.g., the Narmer palette) and ceremonial knives (e.g., the Jebel el Araq knife) and were most likely used in the royal sphere. They suggest that the Egyptians not only imported goods but also took ideas about the representation of kingship from Mesopotamia.

Early Egyptian architecture also displays affinities with Sumerian styles. One characteristic feature of Mesopotamian architecture, the niched facades of public buildings, found its way into Early Dynastic Egyptian architecture. There is also a very general comparison between the stepped towers of Mesopotamia called ziggurats and the great pyramids of Egypt. Both were monumental pyramidal shaped structures, although they differed in materials, function, and form (Near Eastern ziggurats were temples, while the pyramids were tombs). Even so, it is not inconceivable that one was the impetus for the other.

Contacts between Mesopotamia and the Indus civilization are better documented. Known as Meluhha in Sumerian sources, the Indus was a rich supply of goods, especially of carnelian (a hard red stone). One particular type of bead, a carnelian bead etched with a white design, shows the extent of trade already in the third millennium BCE. Examples of this type of bead have been found at many Indus sites, in Iran, Bahrain, Mesopotamia, and recently the Aegean island of Aegina. Several other Indus products have been found in Mesopotamia in small numbers. Some objects combine Indus and Near Eastern features, for instance stamp seals with Indus-style animals with a cuneiform inscription.

The extraordinarily rich Royal Cemetery at Ur (in southern Iraq) dating to the end of the third millennium provides some information on contacts with the Indus Valley and Iran. The women of these burials wore elaborate golden headdresses with gold flowers and rosettes as well as belts made from long etched carnelian beads. The headdresses and belts if not Harappan products were influenced by Indus styles. This is clear from a comparison of these pieces with statuettes of women found at Indus Valley sites. Jack Kenoyer has even suggested that some of the females buried at Ur were servants brought from the Indus Valley itself.

Several features of Harappan culture also indicate influences from Mesopotamia. As in Mesopotamia, Harappan culture emphasizes the bull. Deities are identified by bulls' horns or as composite animal-human monsters, just as in southern Mesopotamia. Despite these comparisons, the Harappan civilization was organized quite differently than Mesopotamia or Egypt. At Harappan sites, unlike in Sumer, there are no remains of what we would identify as a palace or a temple. Instead, there are large ceremonial baths and a focus on providing a clean water supply. While both Egyptian and Sumerian society and economy centered on the palace and the temples, understanding the social and political organization of the Harappan society is more difficult.

Between the two regions of Sumer and the Indus Valley lay Iran and central Asia, both of which were essential links in the overland trade network. It is not surprising, then, that early Iranian culture (called Susa I-II and then Proto-Elamite) was heavily influenced by Mesopotamian art, although it always retained some distinct features. Standing statues from Susa imitate Mesopotamian gestures and dress. Square wall plaques with banqueting scenes found frequently at Mesopotamian sites of the early third millennium were also used at Susa. From Iran came high-quality alabaster vessels and various chlorite vessels.

Vessels made of chlorite (a type of soft stone found in eastern Iran) are particularly useful in highlighting the extent of third-millennium contacts. They have been found in Syria, Mesopotamia, Iran, and central Asia but certainly originated in eastern Iran, with a smaller production site in modern Bahrain (ancient Dilmun). The imagery is quite varied but often includes ferocious serpents, lions, and eagles. They are carved in what is called the intercultural style because some images such as the lion-headed snake derive from Iran and central Asia, while others such as the bull man are more at home in Mesopotamia. The variety of motifs and their appeal to such disparate cultures is an evocative symbol of the mixing of styles and motifs as a result of international trading networks of the third millennium BCE.

Shang Art

China's Shang dynasty (ca. 1600–1100 BCE), which ruled an area in the northeastern region of what is now regarded as China proper in the Yellow River valley, was long considered to be mythical. During the late nineteenth century, however, peasants near the modern city of Anyang began digging up mysterious pieces of bone with notches carved into them. Local legend assumed them to be the bones of dragons. Some of the bones had small pictures and inscriptions carved on them as well. Eventually some of the bones found their way to an antique dealer, who recognized the inscriptions to be a very early form of Chinese writing. The Anyang farmers, hoping to increase profits from the sale of more bones, began to dig deeper until they began unearthing very brightly decorated bronze uten-

sils. China had finally discovered its long lost bronze age.

Later excavations of Shang tombs led to the discovery of a wealth of bronze and other treasures. The artwork of China's earliest dynasties, extending from the start of the Shang period to the early Han dynasty in the third and second centuries BCE, quite often focused on the cult of the dead. Kings and their families as well as other government leaders were very concerned about gaining immortality. As a result they often built and decorated elaborate tombs. Since the Chinese favored burials deep underground, many of their tombs remain. These tombs, especially those of royalty, were fashioned with very intricately fashioned bronze vessels, a variety of weapons including swords and bows and arrows, small and large objects carved from jade, and a variety of ceramic objects. These goods were often placed very near to the coffin to provide comfort and protection to the deceased in the afterlife. The walls of these burial chambers are also highly decorated with a variety of painted or carved ornamental scenes that depict popular Chinese legends or scenes from daily life.

An inventory of the tomb of Fu Hao, from around 1250 BCE, offered many artifacts. Fu Hao was one of the notable women of Shang history and the consort of King Wu Ding. She controlled her own estate and led important sacrificial ceremonies. Her tomb revealed numerous items including:

- 468 bronze objects such as weapons, bells, knives, mirrors, and 4 tigers or tiger heads.
- Over 800 objects of jade, stone, and ivory.
- Numerous bone objects including bone hairpins and arrowheads.
- 11 ceramic objects and thousands of pieces of cowry shell.

Early in the Shang period artisans began to manufacture very high-quality jars and plaques (flat pieces), often inscribed with the names and titles of clans and rulers, that were buried in their owners' tombs. Beautifully carved jade objects as well as woven silk, glazed ceramics, and lacquerware also first appeared in the Shang and were found in tombs as well.

➤ SHANG TOMBS

Shang dynasty kings frequently had very elaborate tombs constructed for them. They were convinced that there was an afterlife and that they could carry their materials to the world of the dead. Shang kings, other members of the royal household, and many members of the nobility often were buried with lavish evidence of their wealth.

One Shang tomb excavated in 1934–1935 was in a deep cross-shaped pit 226 feet (69 meters) long and 147 feet (45 meters) wide. The many funerary items found here included many stone and bone carvings, white-clay ceramic pottery, jades, and bronze vessels. The ceramics and bronze objects displayed finely carved motifs of daily life and animals.

Besides the vast array of beautiful funerary objects, the excavation yielded large numbers of human bones. These were the remains of sacrificial victims who were either buried alive or ritually killed at the time of the king's burial. Those buried alive included soldiers, ceremonial attendants, and the king's servants. Those killed included the bones of at least 59 people who had been decapitated before being placed on the south side of the tomb. It is possible that these were prisoners of war taken during the Shang's frequent military campaigns against neighboring tribes.

—Daniel A. Métraux

It is surmised that the people of northern China had learned from the people of western Asia how to make bronze out of copper and tin and that it took several centuries to develop the highly stylized products of the Shang period. Shang craftsmen produced a wide range of bronze products including mirrors, bells, boxes, and weapons such as bronze-tipped arrows and the bronze halberd, but their most common implements were vessels or jars for wine and food. The bronze jars, vessels, and boxes were quite often cast in molds employing the lost wax technique. Often they were cast in a few different pieces and then soldered together with melted bronze or tin. Early in the Shang period artisans developed a method for using multiple ceramic molds to cast bronze. The

results were remarkable ritual vessels with complex embellishments of figures such as monsters, birds, and humans in relief.

Many of the food or wine vessels were used during the banquets of royalty, but others were employed in various rituals associated with ancestor worship. The most common of all Shang era bronze vessels is the *li* tripod, a bowl having three legs; the shape is unique to the northern areas of China. This tripod design is clearly derived from a pottery cooking vessel used by the Neolithic ancestors of the Shang. The tripod was an extremely practical design for cooking over an open fire.

The bronze version of the *li* tripod was one of several connected with ancestor worship. The pouring of hot wine was an important aspect of these ceremonies. One often finds the most intricate designs on the outsides of these wine vessels. Some of these outside surface designs included intricate and very detailed geometric patterns, silhouettes, and masks of composite dragonlike animals. Many of the vessels come with detailed configurations of birds, animals, and dragons.

The different types were used for at least three purposes: as vessels containing a form of millet wine, vessels containing varieties of food, or vessels containing water. Some vessels with their long tripod feet made it possible to cook the food from the inside using a fire of charcoal under the vessel. Some types, especially wine containers, were made to stand in a charcoal basin.

Another notable Shang art form was carved jade. Chinese legends relate that the original ancestor of the Shang ancestor, born from a great phoenix, was sent to earth from heaven. The result of this legend is that the phoenix became an important motif of Shang jade artifacts. Another important jade motif is that of a dragon. Varying greatly in size and weight, Shang jade artifacts, many of them found in tombs, often include a kneeling person, pigs, sheep, a wide assortment of mythical animals, dinosaurs, jars, and jade plaques.

While upper-class Shang people could afford intricately designed bronze vessels and works of art, the ordinary citizens had to be satisfied with ceramic goods. Shang era ceramics were,

of course, much cheaper and easier to produce, but at the same time they showed many of the same styles concerning shape and decoration as the bronze vessel. Initially, Shang bronze workers often tended to imitate existing ceramic shapes and decoration. Later in the dynasty potters often reflected the influence of bronze ware in their work.

It should be noted that fine work in bronze in China was not just confined to northern areas controlled by the Shang. In 1986, at Sanxingdui in Sichuan Province in western China, other examples of sophisticated work in bronze, gold, and jade were discovered, made by contemporaries of the Shang.

The Art of Ancient Europe

The art of non-Greek Europe during 4000–1000 BCE can be divided into two general categories: mobiliary (easily transported) and petroglyph carvings (rock carvings). The subject matter of this art as well as its role within European society is much debated. Without textual evidence to help interpret this material, much of it remains poorly understood. Yet our poor understanding of this art does not take away from our ability to appreciate the aesthetic value of the works and the technical achievements of the artists.

Petroglyphs are preserved in remote locations in ancient Europe on the walls of cliffs and mountains. There may have been other locations of this art, but over the centuries of European occupation, this ancient art has all but disappeared. More than 100,000 images are engraved into the hard stone of Mt. Beggo located in the Alpes-Maritimes in France. These carvings were carefully incised into the rock using a hammer and soft chisel. About 60 percent of the images relate to bovines; occasionally bulls are yoked and guided by farmers. Some may also be de-

picted enclosed in pens. Weapons and bronze implements make up about 15 percent of the repertoire. Anthropomorphic figures are rare but appear in a variety of poses: raising their arms, pushing a plow, or brandishing a weapon. Val Camonica, located in northern Italy, has a similar variety of images. Of the more than 200,000 images preserved here, some bear traces of ancient paint, testimony to the fact that the viewer would have seen a more colorful image than the modern visitor. The parietal art of Scandinavia bears different motifs. At Bohuslän in western Sweden, men with exaggerated penises wield axes while standing aboard boats. Scholars debate if images such as these reflect narratives of ancient battles or commemorate dances or ritual activities. Petroglyphs are found in many other locations throughout Europe in varying amounts.

The mobiliary art of ancient Europe is quite elaborate. Archaeologists assume that much of this art was produced in wood or other organic media, materials that are not well preserved in the European climate. Among the most elaborate artistic achievements of Bronze Age Europe are pieces produced in metal. Elaborate gold cones (sometimes interpreted as hats or wooden post coverings) have been recovered from France and Germany. These cones are of varying shapes and size, but all bear elaborate registers filled with geometric shapes. Helmets retrieved from Late Bronze Age contexts were not necessarily suitable for protection in battle, and thus they must have served as personal adornments for special occasions. A horned helmet from Zealand in Denmark features a talonlike hook between two circular mounds, likely a nose and eyes. One of the most ubiquitous classes of European art from this period is model carts. Most of these models feature birds or bronze vessels set atop wheels. Perhaps the most curious is the so-called Trundholm sun chariot. Found by a Danish farmer, this piece defies easy explanation. It is a six-wheeled wagon made out of bronze. In the rear is a bronze shield covered with gold leafing (mistakenly interpreted as a sun by early art historians). Standing on the front axles is a bronze horse, seemingly riding the wagon as well. Other classes of art are identifiable as objects for personal adornment, indicating the importance

Trundholm sun chariot. (Gianni Dagli Orti/Corbis)

➤ RECORDING THE PETROGLYPHS AT VAL CAMONICA

In 1956, Emmanuel Anati began working in Val Camonica, a valley in North Italy filled with rock carvings that date from 8000 BCE to 16 BCE. Anati's goal in the valley has been to identify, record, and make sense of these diverse petroglyphs. As of 1995, his team has recorded more than 300,000 rock carvings of varying types and time periods. For the most part, recording these rock carvings is a two-step process. First, students must clean the carving. Often this involves carefully scraping off the moss or grass that may obscure the image, being careful not to damage the petroglyph itself. Once the surface is clean, the students lay a polyethylene sheet over the carving and trace the image directly onto the sheet. This allows the carving to be faithfully reproduced even by someone with minimal artistic talent. Similar processes are used by archaeologists all over the world, most notably in Egypt where an excavator's tool kit often includes a number of polyethylene sheets and markers as well as a trowel.

—Kevin M. McGeough

of individual status in European Bronze Age society.

Mesoamerican Arts and Andes Arts and Crafts

Three major media formed the basis for early arts and crafts in Mesoamerica and South America. These were clay, stone, and textiles. Knowledge of these crafts is based in part on the degree to which they have been preserved in the archaeological record. As such, knowledge of early crafts differs in between the arid coastal deserts of South America and the humid tropical zones of Mesoamerica where the first advanced cultures flourished. In arid regions of Peru and Chile, excavations have produced evidence of craftwork in shell, bone, feather, and gourds. Such materi-

als may also have been common in Mesoamerica but are not preserved archaeologically.

Pottery is one of the earliest documented crafts in both Central and South America, developing about 3000 BCE probably first in north-eastern South America. People in both regions may have used containers fashioned from plain or decorated gourds before they produced pottery vessels. Gourds with designs burned into them have survived in coastal Peru. The earliest pottery was simply made basic forms using organic fiber temper. In Mesoamerica stamping, cord, and fabric impression and incision became common decorative techniques. Inhabitants also developed the use of kaolin clays, which produced fine buff to white-colored pieces. Burnishing was another common decorative technique in South America. Both areas eventually developed slip painting in a variety of colors. People in both regions created clay figurines, predominantly in the form of human females, for use in what were probably shamanic rituals.

Textiles were another common craft item serving both decorative and practical purposes. People in both Mesoamerica and South America made early textiles out of cotton, although South American people eventually favored wool from llamas and alpacas, probably for its ability to hold dyes. Early dye stuffs included indigo, madder root, and cochineal. Cochineal, derived from a scale insect that infests cactus, eventually became one of the most valuable commodities in the Americas. Examples of early textiles have survived in Peru and Chile. In these we can see examples of a number of different techniques including twining, looping, and knotting in addition to simple weaving. Twining, looping, and knotting could produce very open textiles or shaped forms such as hats. Hats created by these techniques have survived in the deserts of Chile. Plain cloth was sometimes embroidered, painted, or stamped to produce sophisticated multicolored designs.

Stone carving became another early craft. Mesoamerica has been specially noted for the production of jade and jadeite sculptural pieces, such as the cache of miniatures from LaVenta and examples of jade masks. Sculpture also includes the oversized heads executed in basalt by Olmec people (1200–500 BCE). There is no

➤ MESOAMERICAN MASKS

A number of exquisite pieces in private and public collections have been referred to as masks. These are slightly oversized representations of human faces, usually made of jade or other green stone. Although the known pieces are all unprovenienced (that is, archaeologists are not sure where they were originally found), they bear unmistakable marks of Olmec art: elongated and/or cleft foreheads, rounded faces, and down-turned mouths. However, the pieces were unlikely to be used as masks by their creators. The eyes, nose, and mouth are solid rather than perforated to allow a wearer to see or breathe. The back of masks tends to be flat rather than hollowed.

What, then, did the creators intend for these pieces? Masks do have perforations at the sides so that they could be tied to or suspended from something. Flattened areas at the back suggest that the intention was to attach the mask to a flat surface. Analogy to later Mesoamerican finds and roughly contemporary South American finds suggest that people created these masks for funerary rituals or ancestor worship.

—Jo Ellen Burkholder

direct correlation for the jade work in the South American sphere at this time other than perhaps small items of shell and bone. Sites such as Huaca de los Reyes, however, bear evidence of large faces carved into the adobe of platform mounds. Unlike the Olmec heads that appear to be lifelike, if stylized, portraits, the oversized images from Peru appear to represent supernatural beings with snarling mouths and crossed fangs.

There is some debate as to whether or not craft production was specialized during this period. Simple textile, gourd, and pottery production was probably within the grasp of most people. However, special skills were needed to carve hard stone such as jade and basalt into ele-

gant forms. Jade in particular is unavailable in the Olmec area, requiring long-distance trade for acquisition. More sophisticated pottery, such as Mesoamerican types produced with high kaolin clays, also required significant technical skill and time to produce.

■ Introduction: Fashion

World fashion varied dramatically throughout the time between 4000 and 1000 BCE. However, the actual production techniques used in the manufacturing of clothing are relatively consistent from location to location. Because the processes of manufacturing garments are remarkably similar, the most important variable is in the kind of materials that are available.

Hides were perhaps the easiest materials to use in the manufacture of clothing in this time. The hides would first be skinned from hunted animals, and then scrapers (stone or metal tools that look like sharp flattened popsicle sticks) would be used to remove any excess tissue from the skin. The skin would then be dried and tanned and possibly dyed (although with hides, this was less common).

Textiles are fabrics manufactured from twisted or spun thread. In this period, most thread was derived from plant products. Plant stalks (for example, flax) were harvested and then retted (soaked in water until the individual strands separated). Then these strands were dried and straightened (and possibly beaten) and then set out in the sun to be bleached. The short threads would then be twisted together to make much larger continuous threads. This process is called spinning, and archaeologists often find

spindle whorls, which were small clay or stone spheres with a hole in the middle, used to make twisting the threads easier. Wool was also spun after it was cut from sheep, and from this point on in the process wool and textiles are processed similarly. These long individual pieces of thread were then woven together on a loom. The warp threads were stretched out on a loom vertically, and the woof threads were woven in and out of these threads until a rectangular piece of fabric had been created. Archaeologists often find loom weights, which look very much like spindle whorls and were used to help stabilize the thread on the loom. Afterward, the fabric was fulled, in other words, shrunk, cleaned, and thickened. This process removes animal oils from wool (which actually decreases weather resistance but makes the fabric smell better). Fulling involves soaking the cloth in some solution, often urine. After this, textiles were sometimes dyed, usually by immersion in a vat of dye, which was usually a very expensive process.

—Kevin M. McGeough

The Origins of Cotton

There are around 50 wild species of cotton (*Gossypium* sp.) native to tropical and semitropical regions. Four have been separately domesticated:

► COLORED COTTON

From the beginning of cultivation in South America there seems to have been deliberate selection to grow cotton of different colors, ranging from brown through mauve to red and through grayish green and yellow to white. Darker-colored cotton was preferred for nets and fishing lines since it was less visible to fish. By the third millennium BCE, naturally colored cottons, along with threads dyed other colors, were used to create patterned cloth with geometric designs including stylized animals and people. In recent centuries the use of naturally colored cottons declined in favor of white cotton, which can be dyed any color, and in some regions naturally pigmented cottons were deliberately eradicated. Almost all cotton grown commercially in the world today is white. Recently, growing concern for the environment and the growing emphasis on organic products have sparked a revival of interest in naturally pigmented cottons, which are now being grown commercially on a small scale in Peru and elsewhere in the Americas.

—Jane R. McIntosh

these are native to Central and South America, Africa (extending into southwest Arabia), and India. In recent centuries the American species have almost completely replaced the Old World species in cultivation across the globe. Today, cotton is planted in spring or early summer and harvested in late autumn. Although winter frosts inhibit the plant's growth they do not kill it, so cotton can also be grown as a perennial bush, a method that was used in the past. Cotton requires a moderate but reliable supply of water, so where rainfall is inadequate cotton must be irrigated or grown on well-watered land.

The wild form of Asian cotton (*G. arboreum*) still grows in southern Sindh and the central Deccan and was probably more widespread in antiquity. The earliest evidence of its use comes from Mehrgarh, Pakistan, where a sixth-millennium grave included a bracelet of copper beads within which were traces of a cotton thread. Later deposits at Mehrgarh, probably of the fifth millennium, included charred cotton seeds. It is not clear whether these came from wild or cultivated cotton shrubs.

Cotton was certainly cultivated by the people of the third-millennium Indus (Harappan) civilization. A scrap of cloth from a bag was found in the city of Mohenjo-daro preserved in the corrosion products from two silver jars. Other Harappan textiles survive as impressions of cotton cloth on metal objects and on the inside of faience vessels, the imprint of rougher cloth and of cord on the reverse of sealings that had been fastened on sacks, and marks imprinted on the base of drying pottery vessels. These show that the Harappans were making cotton cloth of various grades, including very fine closely woven fabrics, all in plain weave. It is likely that cotton cloth was among Harappan exports to Mesopotamia.

The Harappans must have used various colored dyes to decorate their cotton cloth. At present, the only surviving evidence is that the cotton fragment from Mohenjo-daro had been dyed red with madder root and fixed using alum as a mordant. However, other local plants such as indigo and turmeric were probably also used, producing blue and yellow dyes, respectively.

Cotton may also have been grown for its oil-rich seeds. Most plants cultivated by the Harappans were sown in the autumn and harvested in the spring, but cotton was probably grown as perennial bushes on the edges of the active flood plain of the rivers.

After the collapse of the Indus civilization, cotton continued to be cultivated in South Asia. Cotton seeds and occasionally cotton threads are known from second-millennium sites in many parts of the subcontinent. Cotton was probably introduced into Southeast Asia in the late centuries BCE when Indians began to trade there. A discovery in 2007 shows that cotton had reached China at an earlier date: cotton textiles were among grave goods in an eastern Zhou tomb at Lijia. One had been dyed red with vermilion, a pigment used in China for dyeing silk since Neolithic times.

Elsewhere the picture of early Old World cotton cultivation is still unclear. Fifth- or fourth-millennium cotton fibers were recovered from the impression of a textile in the northern Arabian desert at Dhuweila in eastern Jordan, the only cotton known from the Near East before the first millennium BCE. The Dhuweila cotton

could have come from either Africa/southwest Arabia or South Asia. Cotton fibers were certainly in use by this time in the Indo-Iranian borderlands, as evidenced at Mehrgarh. Connections between South Asia and the Near East, although they existed at this date, were extremely tenuous. On geographical grounds, Africa or southwest Arabia might seem a more probable source for the Dhuweila fibers, but little is known of the early history of African cotton (*G. herbaceum*). Third-millennium BCE cotton seeds and lint hairs were found at Afyea, in Egyptian Nubia, in goat coprolites, which shows that goats were grazing on cotton locally, something likely to have been discouraged if cotton was being used by their herders. This is an isolated find: there is no early evidence of cotton cultivation or cotton textiles elsewhere in the Nile Valley, a region with an exceptionally rich archaeobotanical record due to its arid environment.

The earliest evidence of cotton cultivation outside South Asia is in an inscription of the Assyrian king Sennacherib, who planted “trees bearing wool” in his botanical garden in the seventh century BCE. These were a curiosity and seem not to have been taken into cultivation by others; it was many centuries before cotton cultivation became well established in the Near East. Cotton was being grown at Qasr Ibrim in Nubia by the early centuries CE; it is not yet clear whether this was Indian or African cotton. Pliny refers to cotton cultivation in Nubia and Upper Egypt during the first century CE, and it was also grown in Libya, Syria, Arabia, and Anatolia. In sub-Saharan Africa, however, the evidence for cotton cultivation and cotton textile production is much later.

In the New World, two species of cotton were taken into cultivation. *G. hirsutum* is native mainly to Mexico, Guatemala, and the Caribbean but extends into the Isthmus, where it overlaps with the distribution of *G. barbadense*, which grows mainly in northern South America. The two species were separately domesticated.

Much of our information on early cultivation in Mesoamerica comes from the Tehuacan Valley in highland Mexico (an arid region where preservation of organic remains is excellent). Excavations here show that through time, seasonally mobile hunter-gatherer communities gradually

brought a variety of local plants under cultivation and became increasingly sedentary, with permanently occupied villages emerging around 2000–1500 BCE. Two cotton boll fragments, dated around 5800 BCE, and threads possibly of cotton in the Abejas phase (3500–2300 BCE) were found here. Cotton was a well-established cultivar by the Ajalpan phase (1500–900 BCE), and woven cloth survives here from the first millennium BCE. In later Mesoamerica, cotton cloth was generally used for elite garments, while the ordinary people wore clothing woven from maguey (agave) fibers.

However, the world’s most impressive evidence of ancient cotton production comes from the central Andean region of South America, where arid environments have enabled a wealth of textiles to survive, particularly from burials. Genetic evidence suggests that the center of original domestication of *G. barbadense* was in northwestern Peru or southwestern Ecuador. From early times, the inhabitants of northern Chile, Peru, and Ecuador seasonally exploited the exceptionally rich coastal marine resources and those of the valleys inland, and by the third millennium BCE there were permanent settlements in both zones. Plants cultivated in the valleys by the late fourth millennium BCE included cotton. These were traded to the coast where they were also cultivated by some communities, although more commonly the cotton was grown and processed at inland sites. Cotton nets with bottle-gourd floats and cotton fishing lines with shell or cactus-spine fishhooks were essential equipment for coastal communities. Cotton was also used extensively at coastal sites, such as Ancón and Chilca, to make twined or looped textiles as well as bags and slings for hunting. Frequent finds of spindle whorls and needles reflect the processing of cotton. Exchange networks also developed between the lowlands and the diverse regions of the Andean highlands. Cotton was cultivated in the sierra region of the Andes, for example, associated with the complex of ceremonial platforms and other buildings at La Galgada (2200–1200 BCE) where bodies tightly tied in a flexed position with cotton thread were buried wrapped in a cotton cloak or blanket and often wearing a cotton cap. In areas where rainfall or floodwaters were inadequate,

such as in the sierra, small canals were dug to provide water for cultivation. The period 2500–1800 BCE is often known as the Cotton Pre-ceramic since the extensive use of cotton precedes the appearance of pottery in the central Andean region.

Linen and Flax

Flax (*Linum usitatissimum*) was one of the last major crops domesticated in the ancient Near East. Unlike the bulk of the early domesticated plants, flax was raised primarily for something other than food. The fiber from flax was used to produce linen. Until the development of cotton, flax was the key fiber-producing crop.

Linen is a very strong and lightweight textile ideal for the hot climates of the ancient Near East. It is also pleasing to the eye and skin and as a result is still manufactured today. Evidence for linen’s use comes from as early as the Pre-Pottery Neolithic B in Israel (ca. 7000 BCE based on radiocarbon dating of the remains) at the Judean Desert cave of Nahal Hemar, where the dry climate preserved fragments of woven linen textiles.

Linen provided most of the material used in clothing in ancient Egypt and was used in the production of the bandages used in mummification. While not as prevalent in other parts of the ancient Near East, it did supply a substantial amount of the raw material used in producing lighter-weight clothing. Linen was used to make underwear, tunics, dresses, and kilts and was often considered to be of better quality than other materials and so was often worn by the elite of society. In addition to linen’s use for producing clothing, its fibers were used in sail-making and for ropes, while the poorest quality fiber was used as lampwicks in oil lamps that would have been found in essentially every ancient home.

In order to produce linen, the stalks of flax were harvested and then retted. Retting involves soaking the stalks in water to separate and soften the fibers. Once they have been prepared in this way, they are then crushed and beaten to further separate the fibers into a product that can eventually be made into yarn or thread. The beaten stalks were placed in direct sunlight (often on open rooftops) to dry and bleach. The resulting fiber was then combed and spun into yarn, which could be dyed or left white, and woven into cloth.

In addition to its primary use as a source of fiber for textiles, flax also produces a seed that is very high in oil content. While these seeds can be eaten and today are considered a popular

Fragments of linen textiles from the ancient site of Deir el-Medina, Egypt. (Gianni Dagli Orti/Corbis)

healthy dietary supplement, in antiquity the seeds were probably used more commonly for oil production. The resulting flaxseed or linseed oil is not very palatable (it is used primarily today as a base for oil paints) but was used in antiquity as a lubricant; as a basis for resins, unguents, and pigments; and probably most importantly as a fuel for lamps. Its importance would have been even higher in those early periods before the domestication of olives sometime during the Chalcolithic or Early Bronze Age (when olive oil becomes the fat of choice for cooking and other uses). Linen was a major trade commodity for ancient Egypt, and Egyptian linen was renowned throughout the ancient Near East for its high quality.

The Origins of Silk

According to Confucius, Lady Xi Ling Shi, the wife of the legendary Yellow Emperor of China, invented sericulture, the manufacture of silk textiles. One day, the 14-year-old wife of the emperor was sitting beneath a mulberry tree drinking her tea. A silk cocoon fell into her hot tea and began to unravel. The empress realized that the unwinding filaments could be woven into textiles. Her husband, the Yellow Emperor, Huangdi, was one of the Sage emperors and is himself credited with numerous important in-

ventions, and there is no reason to believe that the legend of Xi Ling Shi is anything but a legend. Nevertheless, the earliest clear archaeological evidence for sericulture dates to the third millennium.

In 1927 archaeologists working in Shanxi Province found half a silkworm cocoon that dated to between 2600–2300 BCE. Ribbons, threads, and some woven fragments were recovered from the site of Qianshanyang in Zhejiang Province. These pieces date to between 3600–3000 BCE. Not enough remains of them to learn much other than that they are pieces of silk; the context suggests that they may have been used as the burial shroud for a child. Also from Qianshanyang but dating to about 2500 BCE are about 300 bamboo tools and pieces of silk, all evidence of sericulture. The fragments of silk were woven in a herringbone pattern and consisted of material from at least 20 different cocoons, as fine as silk manufactured today. Much evidence has come from along the Yangtze River. At numerous sites, spinning tools, threads, and woven fragments have been recovered. One ivory cup decorated with silkworms has also been recovered. Clay and stone models of silkworms attest to Chinese interest in the creature, although the function of the sculptures themselves are unknown. This is not substantial archaeological evidence, but it is enough to be certain that by 3000 BCE, the ancient Chinese were practicing sericulture. Characters for silk appear along with the earliest writing, the tortoise shell inscriptions of the Shang dynasty.

The Chinese silk industry has long been based on the exploitation of a blind and flightless moth, *Bombyx mori*. The wild ancestor (*Bombyx mandarina* *Mora*) may not have been blind and flightless, but over centuries of selective breeding the ability to fly has been selected out of the species. Controlling the breeding and feeding the moth appropriate feeds are key aspects of sericulture; it is unclear when these skills were perfected by the ancient Chinese.

One moth will lay around 500 tiny eggs (about 5 grams, or .18 ounces, in total weight) and then die shortly after. These eggs are kept at an ideal temperature until they hatch. The baby worms are then fed fresh handpicked mulberry leaves constantly until they reach an ideal weight.

Once they have reached the appropriate weight, the worms start spinning cocoons. After the cocoons have been left alone for about eight or nine days, they are steamed in order to kill the pupas. Then the cocoon is immersed in warm water, where the filaments begin to unwind. Each cocoon actually has a considerable amount of filament, about 1,968–2,952 feet (about 600–900 meters). The filaments of between 5 and 8 cocoons are twisted together to make a very long thread on a spool. These threads are then woven together to make silk.

Peruvian Textiles

By about 3500 BCE, the people of ancient Peru had developed sophisticated textile production techniques. At this time, cotton became the fabric of choice, replacing the less malleable reeds and rushes that had provided weaving materials in prior periods. By 1800 BCE, weaving had become widespread throughout Peru, with cotton and animal fibers (especially from llamas) being the most commonly used materials.

In the earliest stages of the era from 4000 BCE to 1000 BCE, the most common techniques were twining and looping naturally occurring fibers, such as those found in reeds. Most examples that have been recovered are grass mats often associated with burials. The beginnings of cotton cultivation, starting around 3500 BCE, changed this dramatically. Cotton is much more flexible and allows for the creation of greater varieties of designs. Spindle whorls are also found in the archaeological record around this time, indicating that more effective (and time-efficient) spinning practices had been developed for use with cotton.

Preserved at the site of Huaca Prieta are some of the most interesting designs in early Peruvian

weaving. Barely discernible now (and probably hardly discernible in antiquity) are ghostly bird figures, woven directly into fabrics. Generally, designs in Peruvian textiles from this period are all rectilinear. Given the types of weaving technology available, patterns and figures were produced using straight lines as opposed to curved lines. Even dyed fabrics follow this rectilinear schema. Geometric designs, involving contrasting colors, are very frequent. Birds, animals, and human figures are also readily apparent. Peruvian weavers also seemed to enjoy pairing serpents, fish, and human figures, having the opposing figures twist around each other or interlock with one another.

Between 2000 and 1800 BCE a new technology was developed that allowed textiles to be produced much more quickly and in greater numbers. Called the heddle loom, this new technology allowed the spun fibers to be mounted and separated, allowing for quicker weaving and more complex designs.

Ancient Clothing Styles

Fashion is one of the ways that people identify themselves. This is as true for antiquity as it is today. People of the ancient world dressed according to the fashions of their time and especially of their place. Clothing styles can be very informative. They tell us about a person's origins and status as well as about a society's attitudes toward the body or gender differentiation.

Rarely do textiles survive in the archaeological record. Therefore, our knowledge of ancient fashion is based primarily on painted and sculptural decoration. Third-millennium BCE sculptures from Mesopotamia give us a good sense of Sumerian styles. At this time a heavy fleecy garment made of sheepskin, called a *kaunakes*, became popular. The men wrapped it like a kilt

Statue of what may be a Minoan snake goddess, found in the temple at Knossos on Crete. (Roger Wood/Corbis)

with a kind of bustle in the back, but the women draped it over a shoulder and covered their breasts. Images of women also show that hats and elaborate wigs and hairstyles played an important role in women's fashions. Men were usually bearded with long curly hair, although bald and clean-shaven men served as temple priests. Over the course of time the norm in Mesopotamia became a long tunic and robe of linen or wool decorated with patterns and fringes. Even into the Roman period, Mesopotamia was well known for the quality of its multicolored textiles.

The most prized textiles of the ancient world, however, were Egyptian linen garments. The men in Egypt were generally clean-shaven, and they wore short kilts that fell a little longer in the front. The women, at least the elite women, wore a form-fitting dress with shoulder straps

that exposed the breasts for much of Egyptian history. Almost all of their clothing was of white linen. Clothing in Egypt was also an indication of rank. The more elaborate the garment, the higher the social rank. Of course, elaborate gold and colored jewelry was always in fashion for the rich. In the Egyptian New Kingdom, circa 1550 BCE, long loose gowns that fell in pleats became popular for both men and women. Changes in dress such as these help art historians to date Egyptian wall reliefs.

Perhaps the most dramatic fashions among Bronze Age people belong to the people of the Aegean. The painted women in the frescoes found on Crete and Greece wore elaborate colored skirts that fell in multiple flounces to the floor, sometimes with an apron over their skirts. The sleeved bodice of the dress came around the breasts, leaving them bare, and fit tightly around the waist. Wealthy Minoan women also wore jewels in their hair, which is usually shown long and curly. Men on Crete, at least young men, also wore their hair long so that it fell in curls over their shoulders. They wore short patterned kilts or a garment called a codpiece, an ancient version of the jock strap.

The differences in dress among the Egyptians, Mesopotamians, and Minoans emphasizes the role of costume as a marker of cultural identity. Details of dress were faithfully reproduced in paintings and wall reliefs because dress displayed both social rank and group identity. Like people of today, the people of antiquity often cared about fashion and were sensitive to fashion trends. One Egyptian funeral poem tells us, "She who was rich in fine linen, who loved clothes, lies in the cast-off garment of yesterday."

■ Introduction: Death and Dying

It may seem strange that the topic of death and dying is found in the "Society and Culture" section of this encyclopedia rather than the "Religion and Thought" section. Yet for many of the people of this period, the dead were still members of the community. The practices associated with the treatment of the dead reflected the roles that the dead continued to play in the community and helped mediate the social relationships of those still living. For archaeologists, cemeteries provide some of the best information about ancient social relationships.

Individual graves can tell us much about the society as a whole. For example, Egyptian pyramids, which are essentially tombs, show us the power that the Egyptian king wielded in order to compel people to invest their time, labor, and resources in such a lavish display. Similarly, King Tutankhamun's tomb, which was filled with riches and jewels, showed that the royal family could afford to consign such valuable materials to eternity. The ancient Egyptians would not have seen this as a waste; they felt compelled to provide these offerings to their honored dead.

Studying cemeteries as a whole can also provide important information on ancient social structure. When archaeologists excavate cemeteries, they have certain questions in mind. For each burial they want to determine the gender of the body, the age of the body, how many bodies were entombed together, what types of grave goods were buried with the body, and any other evidence that may shed light on burial practices. When this information is analyzed, it can provide very important insights. For example, if all of the individuals in a cemetery were buried with the same quantities and qualities of goods, this reflects a relatively egalitarian society. If one can

identify differences between the goods buried with males and females, then it may be possible to reconstruct gender roles. If children were buried with huge amounts of valuables (more than many of the adults), this suggests that there was a strong class structure in the society (since most children are not able to accumulate wealth on their own). If only the occasional adult is buried with lavish grave goods, then perhaps status was an important factor in a society (these may have been successful warriors or religious figures). Genetic patterns may also reveal information about families in ancient times.

—Kevin M. McGeough

The Egyptian Afterlife

There was not one simple, unified view of the afterlife that persisted unchanged through the three and a half millennia of ancient Egyptian history. Different conceptions of the afterlife existed side by side in Egyptian theology, a fact that the population seems to have accepted without major question or concern. Sources available for reconstructing ancient perspectives of the afterlife include the remains of lavishly constructed tombs as well as simple graves, mummified human remains and the ritual treatments applied to them, and preserved funerary texts. Such preparations provided the Egyptian who had led a positive life with access to an eternal afterlife. These deceased individuals, who were considered vindicated, or justified (literally "true of voice"), were thus worthy to avoid a second death that would obliterate them completely.

The ancient Egyptians looked in either of two directions for their final destination: skyward to the distant heavens or downward to a remote,

➤ WERE THE EGYPTIANS REALLY OBSESSED WITH THE AFTERLIFE?

The uncertainty of what happens after death is perhaps the most daunting concern addressed by any belief system. The ancient Egyptians are often characterized largely on the basis of their approach to this great mystery. Views regarding death and the afterlife dominate surviving materials. Partial explanation for this situation rests in geography and the randomness of preservation. Areas where the ancient Egyptians went about their daily lives have more frequently been built over, eroded away by a shifting Nile River, or destroyed by human activity as modern civilization has developed. Modern archaeologists have easiest access to remains along the desert margins and farther away from the Nile Valley where necropolises were customarily located. Additionally, large tombs intended as eternal houses for the deceased were often constructed of stone blocks, which preserve well. By contrast, the majority of architecture in ancient Egypt would have been built of mud brick, a much less enduring material. Thus, the modern view of ancient Egyptian civilization is likely somewhat skewed, presenting a somewhat larger discrepancy between matters of life and death than was actually the case.

If the ancient Egyptians are charged with an afterlife obsession, then they are equally guilty of being obsessed with life in general. Indeed, the average Egyptian did not have a lengthy lifespan to look forward to, and many religious and magical beliefs were directed toward improving both the quality and length of one's life. The afterlife was viewed as an extension of this earthly life but effectively as an eternal improved version. Most Egyptian funerary literature and preparation focus on the necessary transitions required to achieve that extended life.

Looking beyond the trials and obstacles of transition, it is notable that the needs and desires

relating to the afterlife itself are surprisingly mundane and are not belabored in texts. The deceased wish to have a household, the companionship of their earthly families, productive fields, perhaps some time for recreation, and the type of lifestyle to which they might have aspired while alive. There is perhaps no other religion in history that emphasizes the preservation of earthly humanity more strongly than ancient Egyptian religion. One quintessentially human desire for the deceased was to avoid working after “retiring” to the Afterlife. This consideration brought about a type of mummy-shaped figure that eventually became ubiquitous in tombs (often in large numbers). Called *shabtis* (“ones who answer”), they were meant to magically substitute for the deceased if called to do fieldwork, a task that paralleled the real world where farming was the most common occupation. A spell sometimes said over the shabti explains their purpose:

O this/these *shabti*,
If the Osiris [person's name] is detailed
for any work that is to be done yonder in the
netherworld . . .
here I am you shall say.
If you are detailed
at any time to serve there,
to cultivate the fields, to irrigate the river-banks, to
ferry sand of the east to the west
and vice versa
here I am, you shall say.

—Nicholas S. Picardo

subterranean underworld realm. In either case, from at least the Pyramid Texts onward the most desired destinations in the afterlife—when put in geographical terms—were The Field of Reeds (aka Field of Rushes) or the Field of Offerings. References to these locales suggest that the afterlife was essentially a reproduction of the earthly Egyptian setting, only idealized as a perfect version. In essence, the eternal paradise that the

Egyptians hoped to attain was the life of a wealthy estate owner, an unsurprising conception of the ideal life given that most sources for funerary religion were generated by the elite and thus reflect their outlook and experiences. This was a place of constant availability of life's necessities, where the well-to-do Egyptian hunted, fished, and oversaw agricultural fields. However, in this vision of Egypt the hunt was

always successful, the fish were always biting, and the fields always yielded a bountiful harvest. No comfort of life was lacking.

Egyptian funerary religion focuses more on the transitions and transformations required to attain the desired afterlife than on extensive details of what awaits upon arrival. The Egyptian conception of the human condition recognized three spiritual elements that, though lacking precise English translations, collectively come close to the modern idea of a soul. These are the *ka*, the *akh*, and the *ba*. Foremost was the *akh*, the effective or equipped spirit that was successful in reaching the desired state of eternal existence. The *ka* was the sustaining energy, or life force, with an individual at birth and surviving through death into the afterlife as a spiritual twin of sorts. Offerings made by the living to sustain the deceased in the afterlife are customarily made for the *ka* of that person. Though likely thought to have been with a person during life, the *ba* emanated primarily after death, acting as the mobile spiritual manifestation that could cross the divide between the realms of the living and the dead. Depicted as a human-headed bird, it was required to return to the tomb and the mummy at night.

A statue of a tomb owner could be set up as a substitute for the corpse in case of damage or loss, but ideally a mummy would be preserved indefinitely. Although there are hints of early attempts to preserve the body from before Early Dynastic times, experimentation that developed into the full process of mummification is usually placed in the Old Kingdom, initially only for the royal family. Elaboration of mummification led to the complex process of drying the body and removing some organs to preserve it from decomposition, followed by wrapping with linen bandages.

Mummification achieved several practical objectives. By desiccating the corpse it accomplished artificially what the dry climate of the desert had done for centuries before the use of built tombs. The body was refashioned in the image of Osiris, god of the underworld and afterlife who, according to Egyptian religion, had been the very first mummy. Just as mummification prompted his resurrection after being killed and dismembered by his jealous brother Seth, the same treatment was expected to facilitate

the rebirth of every dead Egyptian. It also maintained the humanness of the body, keeping it as close to its original form as possible and thus making it an appropriate vessel for the *ba*. This also meant satisfying basic human needs such as eating, drinking, and breathing, which would still be needed in the afterlife. These faculties were restored in both the mummy and tomb statues of the deceased through the most important funeral rite, called the Opening of the Mouth Ceremony, that was performed by a priest or the eldest son of the deceased.

The transition to the afterlife is also expressed in the terms of a cosmic cycle, especially for the king but also for other individuals during some time periods. During the Old Kingdom, a most important transition occurred when the sun's rays provided a ramp or stairway (of which the pyramid shape is often considered a symbol) for the pharaoh to ascend. As the sky was thought to be a body of water, the king joined the sun-god Re in his daily crossing of the sky in a solar boat. The sun set in the western horizon, understood as the underworld realm of the dead, only to emerge, reborn anew each morning at sunrise. The deceased pharaoh could also become a celestial body, specifically one of the circumpolar stars that, from the vantage point of Egypt, never disappeared from the night sky. By the New Kingdom the focus of royal funerary texts changed to the underworld portion of this journey (embodied by the descending underground tombs in the Valley of the Kings), when the king followed Re's perilous nightly course and was reenergized by Osiris in the underworld, providing for rebirth at sunrise and the start of one more day in eternity.

Egypt—From the Pyramid Texts to the Book of the Dead

Ancient Egyptian funerary literature has a long and complex history that probably long predates the earliest known written examples. The genre was fluid, versatile, and constantly changing from its inception. The first known funerary texts are the Pyramid Texts (PT), which were inscribed inside the burial chambers of Old Kingdom pharaohs, starting with King Unas (ca. 2375–2345 BCE) of the Fifth Dynasty.

The PT were used strictly for royal burials and appeared in the tombs of both kings and queens. The texts consisted of a series of self-contained spells or utterances. The pyramid of Unas contains 236 spells. Many of his successors also incorporated new spells, bringing the total number of known spells close to 1,000. Whether the arrangement of the spells within the pyramid is of any significance has been a matter of debate. Some scholars, such as James P. Allen, have argued that they were intended to be read in a specific order. Allen argues that the physical grouping of the spells within the structure of the pyramid was directly related to their specific magical function (for example, the spells along the north wall of the sarcophagus chamber were specifically intended to ensure that the dead king had the necessary provisions for survival in the afterlife).

The PT were intended to ensure that the king (or queen) would safely enter and thrive in the afterlife and achieve immortality through continuous, cyclical rebirth. This was accomplished by magically merging the king's soul with various divine identities, especially Re (the solar deity, whose daily rising and setting was equated with continuous birth, death, and rebirth) and Osiris, who represented the king in death and was associated with fertility and resurrection. The spells were also intended to protect the dead king from the dangers of the afterlife, preserve his physical remains (without which the soul could not survive), and ensure that his soul would have freedom of movement.

In the First Intermediate period (ca. 2160–2055), the sacred texts that had once been the domain of royalty alone became accessible to a wider segment of the population. Several tombs

of nonroyal individuals from this period contain copies of the PT, mostly those that appeared in the tomb of Unas. This trend continued and evolved in the Middle Kingdom (ca. 2055–1650). The spells that had formed the corpus of the PT were adopted, adapted, and vastly expanded upon for use by private individuals, who inked or inscribed them on the inner and outer surfaces of the characteristic wooden coffins of the Middle Kingdom. This new corpus of funerary literature is referred to in modern scholarly parlance as the Coffin Texts (CT). These texts were still restricted to wealthier individuals, since only the relatively well-to-do could afford the luxury of a decorated coffin.

The range of possible spells was vast, and there were many variations of each individual spell. The CT served the same basic functions as their predecessors: they provided protection for the dead and ensured a safe transition to the afterlife. Now, theoretically, any individual—royal or nonroyal, male or female—could assume the role of Osiris in the afterlife. The beneficiaries of these spells were referred to as “the Osiris (so-and-so)” in the texts, thus linking the spirit of the deceased with the god through the magically potent act of equating them in writing. In addition, the spells were intended to provide the dead with many of the same things that people sought in life: provisions, the company of family members, and protection from many of the same dangers that threatened the living (such as dangerous animals and human enemies). Many spells promised the beneficiary an afterlife free from hard manual labor.

The CT also introduced a new element that would become crucially important in the development of Egyptian funerary religion: the idea of judgment in the afterlife. The souls of the dead were thought to be judged by Osiris and a tribunal of other gods. This would be a central theme of the corpus of texts that would come to be known as the Book of the Dead (BD). An additional body of texts and artistic vignettes, also depicted on coffins, emerged in the Middle Kingdom. This is called the Book of the Two Ways by modern Egyptologists, and it described and illustrated the actual physical journey of the deceased into the afterlife, another core concept of the BD.

THE AFTERLIFE IN PICTURES

Detail from the Book of the Dead shows the scribe Hunefer being conducted to the balance by the jackal-headed Anubis, the deity who served as embalmer and guide for the dead. (Jon Bodsworth/The Egypt Archive)

Illustrations of the realm of the dead had already begun to appear as part of the decorations on coffins in the Middle Kingdom in the form of the elaborate maps that accompanied the text known as *The Book of Two Ways*. Images of the afterlife proliferated in funerary contexts from the New Kingdom and remained popular well into the Roman period.

The first pharaohs of the Eighteenth Dynasty were buried in tombs decorated with stylized painted scenes from the *Am Duat* (*Book of What Is in the Underworld*), imitating the simplified drawing style used in contemporary papyrus book rolls. The drawings depict the journey of the sacred bark of Re through the underworld (i.e., the world of the night, where the sun would go when it “died” at the end of each day) and all of its accompanying perils.

The popular *Book of the Dead* was typically illustrated with colorful vignettes depicting the topic of each spell. Tomb walls also frequently depicted scenes of the afterlife, one of the most famous examples being the elegantly decorated Nineteenth Dynasty tomb of Sennedjem at Deir el-Medina. In both cases, the images range from depictions of supernatural scenes, such as the deceased standing in the judgment hall of the gods watching the weighing of the heart, to depictions reflective of the routines of daily life, such as the deceased harvesting grain, walking about freely, or simply sitting down to eat.

—Megaera Lorenz

The BD first emerged in its full form in the New Kingdom (ca. 1550–1069), although sections of it are already attested as early as the late Thirteenth Dynasty, approximately 100 years earlier than the start of the New Kingdom. It was one of several illustrated collections of funerary and cosmological literature that became common at this period. The BD was part of the standard funerary inventory of nonroyal individuals (although individual spells from the BD occasionally appeared on items of funerary equipment from royal burials).

The BD most commonly took the form of an illustrated papyrus scroll, which would typically be placed in the coffin with the mummy with the idea that the vital information it contained would be immediately available to the deceased. The BD contained a series of spells (approximately 189 total, although individual copies varied considerably in the number of spells), grouped roughly by category. The spells have been numbered by modern Egyptologists, although the order in which they appeared in actual copies of the BD was highly variable, as was the actual content of the individual spells.

The spells of the BD dealt with many issues, including the ability of the deceased to safely enter the underworld and retain the physical abilities of the living, the judgment of the deceased by the gods and the vindication of the deceased of any crimes committed in life, the merging of the deceased with various deities (especially Osiris and Re), the ability of the deceased to take on various forms and to be allowed complete freedom of movement, the ability of the deceased to travel in the sacred bark of Re and thus be reborn on a daily basis, and the provision of the deceased with all the necessities of life in the underworld.

The BD remained in use well into the Roman period (30 BCE–395 CE), often supplemented by other funerary books such as the *Am Duat* (*What Is in the Underworld*) and other new books that developed in the funerary tradition. It was never truly canonized, and variations on specific spells were not only accepted but encouraged. The BD, like its predecessors and all other Egyptian religious literature, was part of a living tradition that thrived for the entire period of pharaonic Egyptian history.

The Valley of the Kings

The Valley of the Kings contains the tombs of nearly every pharaoh from Egypt's New Kingdom (Eighteenth through Twentieth Dynasties, ca. 1545–1081 BCE) as well as a small handful of lesser royalty, high officials, and members of the priesthood. The vaguely Y-shaped valley slices through the limestone cliffs to the west of the modern city of Luxor, the site of the ancient Egyptian capital of Thebes. Its modern designation derives from the Arabic name Wadi Biban el-Moluk, or Valley of the Gates of the Kings. As the location of some of the most spectacular monuments in all of Egypt, the Valley of the Kings has been a popular tourist destination since ancient times, as shown by thousands of graffiti left by ancient Greek and Roman visitors in a number of the tombs, which have stood open since antiquity.

It is not known precisely which king decided to initiate construction in the valley proper. In the nearby village of Deir el-Medina, which housed the community of workmen responsible for building the kings' tombs, the pharaoh Amenhotep I was deified and worshipped as the patron and ostensible founder of the settlement. The archaeological record, however, is decidedly unclear on this point, as the Theban tombs of the first four Eighteenth Dynasty pharaohs—Ahmose, Amenhotep I, Thutmose I, and Thutmose II—have yet to be conclusively identified. Fortunately, there are few such problems of identification from the joint reign of Hatshepsut and Thutmose III on-

ward. The tombs of the remaining New Kingdom rulers have now been identified within the confines of the valley, with the notable exceptions of Akhenaten, who chose to be interred in Middle Egypt near his new capital of Akhetaten (modern Tell el-Amarna), and Ramses VIII, whose tomb has not been identified.

A considerable amount of speculation has been put forth regarding possible reasons for the decision to shift the location of the royal burial to the Valley of the Kings. On the one hand, the nearby site of Deir el-Bahri was sacred to the goddess Hathor, whose associations with birth and rejuvenation may have held particular significance for the afterlife of the king. At the same time, the great peak known as el-Gurn ("the Horn"), which dominates the skyline above the valley, quite possibly served as a natural symbolic pyramid for the tombs beneath it. Parallel to this geographical peculiarity was the shape of the limestone cliffs themselves, whose outline resembles the twin peaks and central valley used to write the Egyptian term for the horizon, *akhet*. As the mythical location of the sun's entry into and emergence from the Underworld, the *akhet* was of central importance to Egyptian conceptions of the afterlife. Quite significantly, this same term could be applied both to the royal necropolis itself and to the individual tombs within it. Finally, the isolation of the valley and its relative inaccessibility may have been seen as a potential deterrent to tomb robbers seeking to plunder the cemetery's treasures. However, if the hindrance of thieves was one of the factors motivating construction in the valley, then this goal was never achieved.

All of the tombs in the valley are rock-cut subterranean structures, excavated at a descending angle perpendicular to the cliff face. They differ from most of the earlier pyramid-type royal tombs in that there was no visible connection between the sepulchers in the valley and their respective funerary temples, located along the edge of the cultivation nearer the Nile. In addition, the lack of any substantial built superstructure further distinguishes the tombs in the Valley of the Kings from the pyramids of the Old and Middle Kingdoms.

The basic design employed in the royal tombs of the New Kingdom consisted minimally of an

initial descending stairway or corridor, a second corridor flanked by paired niches, and a burial chamber. To this group was frequently added an additional chamber, or well shaft, whose floor was sunk to a greater depth than the remainder of the structure. In at least one tomb (KV 17, Seti I), this shaft served the practical purpose of diverting destructive floodwaters from the burial chamber, but the wells' probable symbolic association with the primordial ocean and certain regions of the Underworld must also be taken into account. From the reign of Thutmose IV onward, the basic four-room design was frequently doubled, creating the impression of an upper and lower tomb that may have reflected the ancient duality of the royal burial.

Unlike the pyramids, the tombs in the Valley of the Kings exhibit no consistent alignment to the cardinal directions. However, a system of internal alignment was developed, probably during the Eighteenth Dynasty, in which the entrance to the tomb was always located symbolically south, with the burial chamber in the north. Beginning in the Nineteenth Dynasty, this symbolic axis began to shift such that the tomb entrance came to be seen as located notionally east, with the burial chamber in the west. Both systems of symbolic alignment reflected aspects of the mythical journey of the sun god (equated with the deceased king), as also indicated by the ancient names assigned to many of the tomb's chambers, such as "First god's passage of (the sun god) Re, which is upon the sun's path."

Undoubtedly, the most striking features of the New Kingdom royal tombs are the extensive decorative programs employed on their walls and ceilings. These include representations of various divinities associated with the mortuary cult, images of the king, and a wide array of cosmographic scenes and texts depicting the chthonic and celestial regions traversed by the sun god (and, by extension, the deceased king). The use of such texts served to magically associate the tomb with the regenerative powers of the underworld, or *Duat*. At the same time, the architecture of the tomb itself was also conditioned by the layout of the *Duat*, which likewise recalled the association of the valley with the horizon (*akhet*) as the point of convergence between the land of the living and of the dead.

Egypt—The Dead among the Living

Ancient Egyptians did not believe that death severed all earthly ties. The dead were thought to maintain links to the mortal world from the beyond, and deceased individuals were still considered influential members of the community in which they had once lived. They had the ability to exert themselves from beyond the grave, especially through appearances in dreams, and they could also act on behalf of the living in the realm of the dead. The living expressed this ongoing relationship by perpetuating the memory of the dead and attempting to communicate with them directly. Such interactions often happened either at the tomb or within the family home.

A prominent feature of ancient Egyptian religion was the expectation that the living would help sustain the spirits of dead relatives by regularly depositing food and drink offerings at their tombs. Certain holidays, such as the Festival of the Valley, were dedicated to family gatherings at

► A LETTER TO THE DEAD WRITTEN ON A POTTERY BOWL (THE CAIRO BOWL) FROM SAQQARA IN THE COLLECTION OF THE CAIRO MUSEUM

What Dedi presents to the God's Servant Intef, born of Iunakht:

"What about the Maid-servant Imau, who has become sick? Can you not fight night and day on her account against any man or woman who acts against her? Why would you want the destruction of your home? Fight again for her. Set her household in order so that someone will pour libations for you. If there is nothing from you, then your household is done for. Could it be that you don't realize that it is the maid-servant who creates your household from people? Fight for her so that someone will be watchful on her account and so that she will be spared from any (deceased?) man or woman who acts against her. Thus your house and your children will be provided for.

"It is good that you hear" (translation by author).

the relatives' tombs. During the New Kingdom, particular houses were sometimes equipped with their own small shrines or niches that displayed images of family ancestors, to be worshipped and petitioned when it was felt that they could intercede when surviving family members were beset with difficulties. The main objects of this ancestor cult were uniquely shaped statue busts and stelae (inscribed slabs of stone or wood) that depict an ancestor. These family members were often called Able Spirits of Re, suggesting high standing as part of the sun god's entourage that would perhaps make them powerful spiritual allies in the afterlife.

The living also wrote letters to the dead as a more formal mode of communication. Letters were sometimes composed on papyrus or linen, but they were frequently written on ceramic bowls to be deposited with offerings at the tomb in a simultaneous effort to satisfy the relative's

spirit. Such letters identify a problem that is usually attributed to an agent from beyond the grave and request that the addressee intercede. Apparently a case could be brought against such malicious forces in a spiritual version of a law court similar to those found in the mortal world. In some cases the writer believes that the addressee is causing the harm. Common topics include assistance in overcoming illness, redress for wrongful loss of property or inheritance, and requests for children. As incentive for the deceased to comply, some letters hint that future offerings might be withheld if matters do not improve. The writer might also list the good treatment provided when the deceased was alive or remind them of the proper rituals provided upon their death and afterward. This tactic insinuates that the deceased is not fulfilling reciprocal family obligations.

➤ HUMAN SACRIFICE IN ANCIENT EGYPT

It is generally accepted that upon the death of the earliest kings of Egypt, some of their servants were killed and buried with their ruler in order to accompany him in the afterlife. Some early ivory labels may also depict ritual slaughter. Still, a general reluctance among Egyptologists to acknowledge human sacrifice in Egypt has led some to find other explanations, causing most to dismiss any possibility of the practice in later dynasties. Yet archaeological finds at Mirgissa and Avaris clearly point to human sacrifice. Texts from Senusret I, Amenhotep II, Ramses III, and Prince Osorkon explicitly describe ritual slaughter. Evidence for ritual smiting is also coming to light. These examples are calling into question the assumption that human sacrifice was eschewed in ancient Egypt, which has led archaeologists to reexamine some of the practices of ancient Egyptians, along with their own previously held opinions. Currently the evidence does not support the conclusion that there was a regular program of sacrifice, although this cannot be dismissed. However, it is clear that in Egypt human sacrifice was at least used as a response to particular situations, often in response to some type of rebellion against the system.

—Kerry Muhlestein

➤ EAR STELAE—VOICEMAIL OF THE GODS

The deified dead were not the only useful intermediaries employed in ancient Egypt to establish a direct link between individual and deity. In the New Kingdom ear stelae were directed toward the same objective. A stele is an inscribed slab, usually of stone or wood. Stelae were used as tomb or boundary markers, commemorative monuments, and votive offerings. Ear stelae were much like other offering stelae but for representations of human ears applied to them. The number of ears on a single stele varies from 1 to well over 300. Accompanying inscriptions often refer to a god “who hears” or sometimes to the hearing of the ears themselves. The ears are traditionally interpreted as those of the gods, placed on a stele to magically record an earthly message for retrieval by the divine.

The Deified Dead in Ancient Egypt

In addition to cults of state or local deities and private mortuary cults, another type of cult recognized individuals who, although nonroyal mortals in life, were treated as minor deities long after they died. Practically speaking, the maintenance of family cults only lasted as long as dedication from the living permitted. Private mortuary cults could fall into neglect within a few generations. However, some enjoyed sustained devotion from a broader population than just family and lasted many centuries. The offering cult extended beyond the tomb. Shrines, statues, and even temples enacted the formal cult of the deified dead in much the same manner as the cults of gods and kings.

Throughout much of ancient Egyptian history, a deceased member of society was thought to adopt some aspects of the divine upon passing from the mortal sphere of existence into the Afterlife. However, those who gained more extreme notoriety among the deified dead were not merely those whose cults managed to receive sustained attention. Such people were usually quite notable in life, renowned for professional accomplishments (some of which may have become embellished through time) or remarkable wisdom. Commemoration through a formal offering cult was not strictly a means of veneration, however. The deified dead were ascribed a status similar to sainthood. The living considered them close, useful intermediaries who could facilitate communication with gods and goddesses. Cult statues of these influential saint-figures could be incorporated into major festivals, and even royal patronage of such cults is documented.

One very prominent case of the deified dead includes Imhotep, architect of Dynasty III king Djoser. He receives credit for the construction of the Step Pyramid at Saqqara in the early Old Kingdom, the very first royal pyramid. His reputation is also one of the most long-lived of any nonroyal Egyptian, due in part to his eventual deification. By the late New Kingdom he was still remembered as a man of knowledge and letters. Deified status followed thereafter with the erection of temples dedicated to him. In still later times under the Greek occupation of Egypt, an association with medicine and healing caused him to be equated with the Greek medical god Asclepius.

At the southern Egyptian site of Elephantine (at modern Aswan) are the remains of a sanctuary devoted to a prominent provincial governor named Heqaib, who lived during the Sixth Dynasty of the Old Kingdom. He was known in life especially for successful trade expeditions to the south on behalf of the king. Statues, votive items, and additions to his sanctuary indicate that his cult was well maintained through at least the late Middle Kingdom.

Formal cults to the deified dead became especially widespread in the Late period and after.

The Kerma Cemetery

Nearly two miles (3 kilometers) east of the ancient city of Kerma (in present-day Sudan, ancient Nubia) lies a cemetery almost 148.2 acres (90 hectares) in size that contains numerous small

graves, some very large graves including elaborate tumulus graves and two funerary temples for ritual practices. Many of the grave goods are Egyptian in style, and much of the belief that justified the huge expenditure of labor and resources on these funerary monuments must have been based on Egyptian practices. However, the cemetery is uniquely Nubian, representative of the kingdom that the Egyptians called Kush. Kerma was Kush's largest site and arguably was the first city in Nubia. Its use, based on the dates of Egyptian objects found in association with the cemetery, was roughly coincident with the Egyptian Second Intermediate period.

The most elaborate tombs are the eight tumuli located on the southern edge of the cemetery. A tumulus is a large mound of earth or sand set atop an underground chamber. The largest at Kerma are 98.4 yards (90 meters) in diameter; the dirt tumuli of these tombs are supported by a series of mud-brick walls that run perpendicular to either side of the burial chamber. In three of these tumuli, the burial chamber was a long central corridor that ran the length of the tomb. While most of the grave goods had been looted long before the modern excavations of George Reisner, much of the layout was still intact. Each of the eight largest tumuli had a central burial chamber; one had a coffin made of quartz, and another had a coffin made of slate. The three tumuli with the long central corridor were filled with the bodies of retainers sacrificed for service in the afterlife. These sacrificial victims numbered in the hundreds. Associated with these larger tumuli are smaller satellite tumuli. These satellites are smaller than the main tombs but feature some elaborate artifacts; scholars are divided as to whether these were royal family members or high-powered court officials (or both), since unlike Egyptian tombs there are no written explanations provided in these tombs.

The vast majority of burials are simply oval or rectangular pits cut directly into the ground and covered by a very low tumulus. The bodies are laid on their right side, in a flexed position, facing north. The bodies rested on a wooden bed, buried with slippers and a headrest, covered with an animal hide, and provisioned with various animals and beverages for use in the afterlife.

Some of these simpler burials were associated with sacrificial victims as well, servants killed for their superior's use in the afterlife.

Tumuli burials, like those found at the Kerma cemetery, are also found at other Kerma culture sites. While none are as elaborate as those of the Kerma cemetery, they are similarly built and equipped. Male graves commonly include weapons. Daggers and swords are found in many male graves. Archers were also buried with their equipment.

➤ WHY CHILD SACRIFICE?

Why, in a culture where animal sacrifices were normative and usually sufficient for most purposes, would one sacrifice a child? The theory that child sacrifices offered a way to control family size with added divine benefit has been presented, but it remains questionable. It is more likely, as A. R. W. Green notes, that child sacrifice granted a benefit beyond that of sacrificing an animal. Since a child was much more valuable than an animal, the sacrifice would have been seen as more significant. Because of this, child sacrifice was likely used in times of great need or at especially important sites, such as high places or city gates.

Babies under the Floor— Canaanite Burial Practices and the Issue of Child Sacrifice

Certain burial sites from Canaanite settlements have been theorized as being the remains of child sacrifices. Of concern are infants and young children interred in jars occasionally with small amounts of grave goods, such as bowls or jugs, and placed within floors or walls. These burials are the focus of scholarly debate about whether they represent child sacrifices to bless homes and sacred sites or a culturally accepted burial custom for young children and infants.

Such burials were first identified as child sacrifices by R. A. S. Macalister in the excavation report from the site at Gezer. Macalister identified these burials as child sacrifices to sanctify a holy site, or high place. The religious importance of such sites is well attested in Canaanite sites. In later excavations at Gezer, the jar burials were not found to be contemporaneous with the use of the high place or its construction. Instead, the infants were likely gathered together in a specific place that served as a graveyard. The high place was then developed at the same site in a later period.

The recognition of the Gezer burials as having resulted from natural deaths has raised questions concerning the practice of child sacrifice as a means of sanctifying building sites within the Canaanite culture. Since the Gezer excavations, there have been other child jar burials found under foundations and walls in Canaanite sites. Generally, they have been regarded as fulfilling a normative interment tradition, placing newborns and young children close to the hearth. The presence of such burials in numerous sites may just reflect the child mortality rate in the Canaanite sites.

While many jar interments have not been seen as sacrifices, there remain some individual burials that may reflect these practices. One such burial was found in the site of Dothan, where a child of one-and-a-half years of age was discovered beneath a large individual square slab of stone that was part of a wall dated to the Middle Bronze Age. Another wall burial was found at Tell el-Farah, which is located near Nablus. This burial consisted of one infant interred in a jar

and a hollowed-out location for a second infant against a Middle Bronze Age gate. It has been noted, however, that the hollow area in the gate could have been prepared after construction, which would limit the likelihood that the infants were a foundation sacrifice.

The sacrificial basis of burials, such as those at Tell el-Farah and Dothan as well as others at Negeb and Jericho, remains heavily contested by scholars. There is little evidence that they were more than burials of individuals who died of natural causes. This in conjunction with the reevaluation by William G. Dever and others of the Gezer high place calls into question the practices of child sacrifice to bless foundations within the Canaanite culture. The possibility that this practice was present cannot be ruled out, but within most sites it has become questionable.

The Greek Hearth

The Greek hearth was a fixed, slightly raised area often rectangular in shape of about 3 feet (1 meter) across and coated with plaster, clay, or stones designed to contain the family fire within the home. The hearth fire stood in the open center courtyard or was sometimes built near the entrance in the vestibule. It was a focal point of Greek life. Near the hearth, slaves and women of the family attended to their household duties that included spinning, weaving, and preparing meals. It was the home's practical and symbolic center where families cooked food, kept warm, and received light and functioned as the axis of familial religious activity.

The Greek word for hearth is *hestia*, which is also the name for the goddess believed to dwell within it. The head of the household sacrificed at the hearth before every meal. The hearth fire was considered sacred and was kept burn-

ing throughout the year. New members of the *oikos*, or family, such as babies, brides, and slaves, experienced their ritual introduction at the hearth. On the fifth day of life, the newborn child circumambulated the hearth in his or her father's arms in a festival called Amphidromia. On the day of betrothal, the bride was led by her father from his hearth to that of her new husband. Slaves were brought to the hearth the day they fell under the authority of their new master. Thus, the hearth was sacred to the Greek sense of family unity and identity. Socrates in the *Cratylus* (401b) relates the Greek proverb "Begin from the hearth," which meant a propitious start to any undertaking. The hearth and its undying fire symbolized permanence of the family and the divine presence of the goddess.

Like the domestic hearth that was the center of the home, the Greek city-state had its own civic hearth where the members of many families gathered at the single public cult of Hestia. Thus, the civic hearth helped to create a sense of community beyond that of the *oikos* and certainly helped substantiate the ideals of democracy in Athens. It also served an important diplomatic function since foreigners from different city-states would be honored there as guests. In a similar vein, the civic hearth functioned as a place of refuge for those seeking asylum since it was considered sacred space and as such was protected from hostile intrusion by the threat of ill-omen. The temple at Delphi had its hestia at the center and was considered the communal hearth for all of Greece and as such helped foster feelings of Pan-Hellenism, at least when city-states were not at war with each other. It was from here that the most sacred of fires would be brought to the new hearth. In Argos when the head of the family died, the hearth fire was extinguished, and a new unpolluted flame was brought in from the fire at Delphi. The goddess Hestia was considered to dwell in all these hearths, working to keep the main social units of family, polis, and Greek as a series of interlocking communities.

The hearth was essential to the lives of ancient Greeks since it defined them as civilized people. Without a hearth, a human is a wanderer and vagrant, without attachment to a family, city-state, and the sacred fire. With the hearth fire,

people dwelled with the great goddess Hestia and her promise of concord. Without a hearth, a person was no better than a beast that dwells in the outskirts of town away from the comfort of family, community, and the gods.

Minoan and Bronze Age Greek Tombs

Two styles of tombs were prevalent in Crete (the home of the Minoan culture) in the Early and Middle Bronze Age; they might be characterized as square and round. The square variety was more prevalent, appearing in different manifestations from Palaikastro to Gournes to Arkhanes to Mochlos. These were either square or oblong rooms or a series of narrow rectangular chambers arranged parallel to each other. Some scholars suggest that these square tombs should be regarded as house tombs and that they served as houses for the dead.

Located only in southern Crete in an area called the Mesara were the round tholos tombs. These were slightly more elaborate in construction, combining a rubble core with a rock facing. The entrance was always to the east, probably in association with the rising sun. Whether or not these structures were roofed is still under debate. Inside, the structures had a slight corbel vault, meaning that the rocks came closer together as they rose above the ground. For large structures, the only way to secure such vaulting was with a capstone at the very top, meaning that the cor-

beling had to go all the way up. Such a roof has never been preserved among the tholoi of the Mesara, so it is impossible to tell if all their roofs have simply fallen in, if the corbeling went up only a short distance before being covered over by a reed roof, or if the tombs were simply left open to the sky. These structures were large enough for several burials, and they were used repeatedly over several generations, occasionally having the insides burned as a form of house-cleaning. The ultimate form of the tholos appeared much later and much farther to the north when the Mycenaeans adapted the Minoan practice for their own nobility.

Before that occurred, however, the Bronze Age Greeks had their own styles of burial. Simple inhumations in cist graves generally served in the Early and Middle Bronze Age. A cist grave was a rectangular chamber dug into the ground and lined with slabs of rock to support the shape. A bedding of pebbles could line the floor, and the interred might be laid out in a crouched position so that a smaller cist would suffice for burial. With the coming of the Mycenaeans (or at least their newfound wealth), a more elaborate style was used, specifically the shaft graves of Mycenae. These were improved cist graves in which the cist was deepened and enlarged to accommodate up to three people, and the walls were given additional supports to keep them from falling in on the dead. Finally, the grave was roofed over with stone. Several such shafts are arranged together in Grave Circles A and B at Mycenae, with the circles themselves covered over with earth and the individual graves marked by sculpted stelae.

► THE TREASURY OF ATREUS

For true ostentation, nothing beat the Mycenaean tholos tombs of the Late Helladic III period. These structures were the result of a natural evolution of the Minoan tholoi. Several smaller tholoi appeared in Greece during the Mycenaean period. All were round, and at the time of discovery all of their roofs (these did have roofs) had fallen in. But in the Late Helladic II, these structures took on monumental proportions. One of the later examples, the so-called Treasury of Atreus, for example, measured 15 meters in diameter and in height. The interior was entirely lined with sculpted stone and was originally decorated with gold wall ornaments. A separate rectangular room jutted off from the circular tholos where, past a door, the body was laid to rest. Grave robbers were prolific in the Bronze Age (and also in the Victorian era), and every attempt was made by the Greeks to protect the grave and its goods. Despite their attempts, however, nothing now remains of the treasure, but both the side chamber and the tholos were probably filled with elaborate grave goods.

Located 90° from the burial chamber was the tholos entrance, comprising a door almost 10 meters high capped with a lintel stone weighing several tons. The entire portion of the tholos below the level of the lintel was dug into a hillside along with a 36-meter-long dromos, or corridor, leading to the entrance. The face of the doorway as well as the dromos walls were lined with large regularly cut rectangular stones. Above the level of the lintel was the corbel vault, giving the tholos the nickname “beehive tomb,” as on the interior such corbel vaulting looked like a beehive. This kind of vaulting stayed in place through conflicting pressures: pressure that the cut stones placed on each other and pressure that the surrounding earth placed on them from above and around. For this reason, it was imperative that the vaulting be buried. If the ground above the capstone eroded

The Treasury of Atreus in Mycenae is actually a tholos or beehive-shaped tomb. The structure was identified and named by the second-century-CE traveler Pausanias. (Corel)

away, the capstone eventually fell in, and the entire vault came undone.

On all the walls except the doorway, the corbeling was pretty much continuous from floor to capstone, so no one stone had to bear very much weight. This was not the case with the lintel, however, that had nothing below it for support. To relieve this stone (which is already quite heavy) of some weight, the Mycenaean architects developed the relieving triangle, a hollow triangle directly above the lintel. This triangle was covered with decoration so as not to be visible from the outside. Of course, grave robbers inevitably knew that it was there, and this was the main form of illicit access into the tholoi.

The treasury's façade was elaborately decorated with sculpted stone imported from Egypt and is now on display in the National Museum in Athens. Once the entire complex was filled and finished, it was buried so that only a hill was visible. It might be called a rather inconspicuous form of conspicuous consumption.

Royal Cemetery of Ur

The excavation of the Royal Cemetery of Ur was one of the earliest and most spectacular discoveries in the world of Near Eastern archaeology. In 1922 Sir Leonard Woolley, a British explorer and archaeologist, was laying trenches in the fabled city of Ur, a large tell (a mound containing

the remnants of previous settlements) in the southern Iraqi desert and the birthplace of the biblical Abraham. What Woolley found, the burials of the kings and queens of Ur, continues to shock and fascinate us today. Buried beneath the sands was a large burial ground for the city of Ur during a period called the Early Third Dynastic

Carved gold helmet that belonged to Meskalamdug, a king of Kish and Ur, 2450 BCE. (Scala/Art Resource, NY)

period, circa 2600–2400 BCE. This was a period when kings gained absolute power in southern Mesopotamian cities such as Ur, and they built great temples and palaces to advertise that power.

Most of the more than 1,000 burials that Woolley excavated at Ur were simple human burials (referred to by archaeologists as inhumations), where the body was wrapped in a reed mat or coffin and placed in a rectangular pit. Sixteen tombs stood out both for their carefully built burial chambers and the wealth of their burials. These came to be known as the Royal Tombs. Several of the cylinder seals and objects found with these burials name a king or queen, seemingly confirming Woolley's royal identification.

The royal tombs were large vaulted stone-built chambers, usually with a ramp leading up to them. One of the most unusual features of these graves was the large number of sacrificial victims buried with the main occupant of the tomb. One burial had 63 retainers, or court officials, buried in a large pit in front of the tomb chamber, and another tomb had 73 retainers. Most of these victims were young women opulently dressed with exotic and expensive golden headdresses. At the entrances to some of these tombs, male skeletons with helmets and spears

or daggers and whetstones lay where they had stood guard.

Woolley found small cups next to many of these retainers, who had come down to the tomb with the funeral bier where they drank (or were forced to drink) some kind of poison. In addition to the large numbers of people buried with each royal burial, the numbers and wealth of the objects included in these burials were staggering. The elite themselves were dressed in elaborate jewelry and gold headdresses, and with the bodies were cylinder seals and sometimes weapons. Hundreds of beautiful objects, some of the best examples of Sumerian art, were taken from these tombs. One is a delicately carved gold helmet that belonged to a Meskalamdug, a legendary king of Kish and Ur. Other famous pieces are the four-foot-tall wooden lyres decorated with gold bull heads and inlaid shell.

Many of these objects, like the lyres and wooden and silver sledges, would have been used in the burial ceremonies for the transport of the body and the playing of music. Many others were probably for the dead king or queen to use in the afterlife.

These objects represent the absolute best in Mesopotamian craftsmanship. The metalwork and especially the jewelry show the mastery of complex gold-working techniques, such as repoussé (a technique whereby metal is shaped or ornamented with patterns in relief made by hammering or pressing on the reverse side). The range of materials used to fashion the objects also demonstrates the wide-ranging trade contacts that the kings and queens of Mesopotamia had already established at this early date. All of the precious materials in the tombs—the shells, gold, silver and lapis lazuli—were imported from the Gulf states, Egypt, Anatolia, and Afghanistan. Certain luxury objects, such as ostrich eggs, chlorite vessels, and large carnelian beads, came from as far afield as Egypt, Libya, eastern Iran, and India.

The Royal Tombs of Ur also give us an extraordinarily clear insight into one very important aspect of Mesopotamian society: their attitudes toward death and dying. It is certainly clear that the rulers of Ur put an extraordinary amount of effort and wealth into their burials. How can we understand these burials and what appears

► THE ROYAL CEMETERY OF UR—TEXT AND ARCHAEOLOGY

Several Sumerian texts can shed light on the archaeological phenomenon of the Royal Cemetery of Ur and demonstrate the complementary nature of both bodies of evidence, text and archaeology.

The first is a poem about the great hero Gilgamesh, one of the legendary kings of Mesopotamia. The poem, titled *The Death of Gilgamesh*, describes his death as follows:

“His beloved wife, his beloved son,
His beloved favorite wife and junior wife,
His beloved singer, cup-bearer and . . . ,
His beloved barber, his beloved . . . ,
His beloved attendants who all served (in) the
palace,
His beloved consignments—
When they had lain down in their place with (him),
as in
The pure palace in Uruk, Gilgamesh, son of
Ninsun,
Weighed out the meeting gifts for Ereshkigal,
Weighed out the presents of Namtar.”
(Tinney 1998, 27).

The poem seems to suggest that Gilgamesh’s crossover to the underworld included his family members and attendants laying down with him at his burial.

A second poem belongs to a famous woman poet, Enheduanna, who lived several centuries later than Gilgamesh, around 2000 BCE. The poem starts out with Enheduanna cursing the city of Uruk. The last few lines of the poem refer to mourning practices perhaps demonstrated in the Royal Tombs of Ur:

“Oh lady, the (harp of) mourning is placed on the ground.

One had verily breached your ship of mourning on
hostile shore.
At (the sound of) my sacred song they are ready to
die.”
(Woolley and Moorey 1982, 93).

Could the harps that accompanied the attendants into the death pits at Ur have played the sacred song of Inanna and heralded their impending deaths?

A third poem, *The Death of Ur Nammu*, was written circa 1800 BCE. The text lists the sacrifices that Ur Nammu made and the offerings and gifts that he presented to the gods of the underworld. These parallel the vast numbers of goods found in the Royal Cemetery of Ur. Were these goods the offerings and presents needed for the kings of Ur to gain entrance to the underworld, as Ur Nammu’s text suggests?

The texts, although all later in date, can help us understand Mesopotamian death rituals and provide possible explanations for the phenomenon of the Royal Cemetery of Ur.

to us as the gruesome practice of mass human sacrifice?

Woolley described the Royal Tombs as a burial site in which all of the court—the soldiers, servants, musicians, and grooms—all descended to their king’s or queen’s tomb, where they drank of some potion and willingly laid down their lives to serve their lord in the afterlife as well. Since Woolley’s discovery, others have suggested competing theories to explain this extraordinary

phenomenon. One theory has it that the kings and queens buried there were playing out a famous Sumerian myth about the sacred marriage of the Mesopotamian god Dumuzi, king of the Underworld, and the goddess Inanna, goddess of fertility and war, to ensure the fertility of the land. Others suggest that the burial of extraordinary riches and his court was a powerful way for each ruler to demonstrate his wealth and his control over others’ lives.

Although the practice of human sacrifice did not survive long after the Royal Cemetery of Ur, it was practiced in other early societies in Egypt, Sudan, and China. In all these cases, the court retainers were considered part of the possessions of the king and queen, and their services would surely be needed again in the afterlife. The same principles may have been at work in Ur.

Burials in Neolithic China

Burial customs in the Neolithic period in China varied considerably from region to region. In the early part of the Neolithic at the site of Banpo, joint burials and family tombs were the norm. Typically these were secondary burials, meaning that the deceased were deposited elsewhere initially, only later being brought into the family/joint tomb. The tombs are filled with members from different generations who died at different times. Adults tend to be buried separately, although female children are buried with adults at the near-contemporaneous cemetery at Yuanjunmia. Changing gender roles at Banpo are apparent through the study of different grave goods. In the earliest use phases of the cemetery, men were buried with tools for fishing and hunting. Women were buried with tools used in agriculture and clothing production. These grave goods probably reflect the roles that the individuals played in life. As the period progresses, men start being buried with agricultural equipment, and there are significantly more tools than women. It is usually impossible to understand how the inhabitants of the Banpo family tombs related to one another. This is not the case at Dawenkou, where couples are often buried together (men on the left and women on the right). Gender roles are also apparent at Dawenkou, where men are given considerably more space in the tomb, while women

are relegated to the corner. Graves at Dawenkou are simple pit graves. A smaller and deeper pit is dug into a larger pit. In single graves, the body of the deceased is placed in a coffin and buried in the deeper interior pit. Grave goods are placed throughout the shallow pit.

A different mortuary tradition is in evidence at the site of Xishuipo in Puyang in Henan Province. As with Banpo, the site of Xishuipo is associated with the Yangshao culture. Unlike Banpo, status differentiation is apparent in the burials at Xishuipo. Most remarkable is Tomb M45, the final resting place of the so-called Puyang Shaman. The tomb consists of three main sections (each with a human body), with the Puyang Shaman in the middle section. He was found laid out on his back in between two clamshell inlaid images; on his right is a dragon, and on his left is a tiger. Two other clamshell animal designs were found north of M45, depicting tigers, deer, dragons, spiders, and mythical creatures. Scholars have speculated on interpretations of this complex; some have suggested that these designs must reflect some sort of sacrificial practice.

The burials at Xishuipo are not the only burials from Neolithic China that seem to be associated with ceremonial centers. Piled stone grave mounds, associated with the Hongshan people, have been excavated from near what is thought to be a temple at Niuheliang. Excavations of some of these burial mounds have revealed an uneven distribution of grave goods; some of the bodies are not associated with any grave goods at all. Those goods that were recovered were not utilitarian goods like those found at Banpo. Rather, these were elaborate jade objects used for personal adornment, ritual or religious purposes, or both.

In the latter half of the Neolithic, social differentiation is even more readily apparent. The remarkable burial excavated at Sidun in Jiangsu attests to the developing social stratification in Neolithic China. Called Tomb 3 by the excavators, this burial contained more than 124 grave goods, most made of jade. Thirty-three *cong* were found in the burial. These are white jade cylinders (squared on the edges), at most about 13 inches (35 centimeters) in height. These *cong* bear a common Liangzhu motif, two eyes that

seem to represent a deity. In some cases the eyes are depicted as part of an animal-like face with feathers for hair. The functions of these objects during this period are unclear. Twenty-four *bi* were found in Tomb 3. Also distinctive of Liangzhu culture, *bi* are small white jade disks, at most 10 inches (26 centimeters) in diameter, with a hole in the center. Other remarkable Liangzhu-era tombs have been excavated. Tomb M12 from Fanshan in Zhejiang produced what has been called the “king of the *cong*.” It weighs 7.7 pounds (3.5 kilograms) and features a more elaborate form of the typical *cong* iconography. Also from M12 is a jade ax, known as a *yue*; this particular *yue* bore the same iconography as the “king of the *cong*.” Other *yue* recovered from funerary contexts bear inscriptions of birds sitting atop pedestaled structures, with distinct icons in the center. Some scholars have taken these as signs of clans, lineages, or ruling houses; they are remarkably similar to Egyptian *serekhs*.

The large cemetery at Taosi, which was in use from 2600 BCE until 2000 BCE, reflects a highly stratified culture where personal wealth varied dramatically. Although there are likely at least 10,000 bodies interred at the site, only about 700 have been excavated. Of those, 600 were classified as small graves, 80 were medium-sized graves, and 6 were large graves. The small graves were very shallow rectangular pits, just large enough to fit a body without a coffin. A few of these graves have some grave goods, but most have none. The medium-sized tombs are also rectangular, and usually the deceased is buried in a wooden coffin (sometimes a man and a woman are found in these burials). The excavators further subdivide these medium-sized tombs based on the wealth of grave goods. Most have some mortuary objects, but the type and number of goods varies considerably. Finally, the six large tombs are rectangular and substantially larger 9 feet (3 meters) by 6 feet (2 meters). Wooden coffins were placed on floors covered with cinnabar. Amounts of grave goods run from 100 to 200 objects, most of high quality and many of unusual style (for example, wooden drums covered with crocodile skin, pottery with dragon designs, and stone chimes).

The Shang Cemetery at Xibeigang

The cemeteries at Anyang (ancient Yin, the Late Shang capital) have been well studied. A royal cemetery was located at Xibeigang at Anyang; while most of the tombs had been looted, the basic layouts and architecture of the tombs was preserved. There are 13 tombs that archaeologists associate with the royal cemetery. All are

A Chinese archaeologist works at a newly-discovered pit of chariots and horses in the ruins of Yin, just outside present-day Anyang in central China's Henan Province. Five of the seven pits are arranged in a line, with chariots and horses facing eastward. Yin was an ancient name for the Shang dynasty. (Corbis)

► THE TOMB OF FU HAO AT ANYANG

The only individual known from historical accounts of the Shang dynasty whose tomb has been discovered (and identified) is Fu Hao, the consort of Wu Ding, one of the Shang rulers. Bronzes in her tomb bear inscriptions of her name. Located in Anyang, this tomb, which is 8.2 yards (7.5 meters) deep, had been flooded, so the wooden coffins and remains of the deceased were not well preserved. However, 1.7 tons (1,600 kilograms) of bronze objects (more than 200 pieces) were recovered, as were 755 jades, 564 carved bone objects, and a variety of other grave goods. The large bronze objects were arranged around the edges of an outer coffin, and the jades were placed within an inner coffin along with more than 7,000 cowrie shells.

—Kevin M. McGeough

oriented to the northeast, and all feature long sloping ramps that lead to deep vertical shafts. At the bottom of the shafts is where the deceased and associated grave goods and sacrifices were interred. Since many of these shafts are beneath the water table, preservation and archaeological recovery have been minimal. The most frequent class of grave goods in these tombs is military equipment; each tomb seems to have had a vast amount of equipment, including chariot fittings.

Tomb M1001 at Xibeigang is somewhat unusual in that it has four ramps that lead down to its main chamber. The chamber is also cross-shaped, with a wooden installation in the center. While no coffin (or body) was recovered from the tomb, it is likely that it would have been placed in the center. Around the outside of the chamber were nine pits with human sacrificial victims. After or during the funeral ceremony, the chamber was filled with earth and more human sacrifices. The ceremony was particularly violent given the large number of sacrificial victims found within. Along the south ramp, 59 headless skeletons and 42 skulls were found. Most of these were teenage boys; their arms had been tied behind their backs, and they had been lined up and beheaded. Thirty-one sacrificial pits were found outside the tombs as well. Twenty-

two of these had human remains (ranging from one to seven bodies in each). A few also had horses and other animals. The funeral for whoever had been buried in M1001 was certainly a conspicuous display of power.

Thai Metallurgy—Burials at Non Nok Tha and Ban Chiang

Prior to the 1960s it was widely believed that the earliest metal use in Southeast Asia dated to around 500 BCE. New data, however, suggests a much more advanced civilization, evidencing metallurgical technology dating much earlier. These findings in the northeastern region of Thailand point toward a technologically sophisticated civilization and demonstrate complex social organization. In addition, the metal usages, as well as art, pottery, and agricultural practices, help to identify possible contacts and influences from outside cultures. Two excavated sites in Thailand, cemeteries at Non Nok Tha and Ban Chiang, have been extremely useful in providing evidence of innovation and advanced civilization from within indigenous civilizations of Southeast Asia.

The excavation of the cemetery at Non Nok Tha represented one of the first and largest excavations of its kind in Southeast Asia and resulted in the unearthing of more than 200 samples of human remains. These findings helped researchers conclude that there had been intermittent

human habitation in the region since 3500 BCE. Archaeologists also uncovered some of the oldest evidence for rice cultivation. In 1966 archaeologists discovered bronze fragments at Non Nok Tha, revealing one of the oldest and most sophisticated copper tools used presumably in agricultural practices. The discovery of bronze in Thailand changed many conceptions of the local development of bronze metallurgy. Likewise, discovery of agricultural practices contradicted prior notions of their origination in the Middle East. The site revealed evidence of bovine domestication, indicating advanced and innovative use of water buffalo in rice cultivation. Recent reevaluation of the radiocarbon dating methods used to argue for these early dates has suggested that bronze manufacturing this early at Non Nok Tha is unlikely. The more accepted dates now range from 1500 to 1000 BCE, which is still significantly earlier than what had previously been believed to be the case in Thailand.

The second site at Ban Chiang, excavated between 1974 and 1975, was initially interesting because of pottery discoveries. The site became increasingly important as bronze jewelry and tools dating to around 2500 BCE were excavated. While some dates have been contested and most now believe that the metal objects are better dated to around 1500 BCE, the findings themselves were important in reevaluating the history and influence of the region. Artifacts and human remains were found at the site dating to both the Bronze Age and the Iron Age. Potsherds found at Ban Chiang indicated advanced artistry as well as individual creativity. The time-consuming patterns and designs are detailed, suggesting what some believe to be an indication of leisure as well as the development of skill. It is believed that Ban Chiang was settled around 4000 BCE. Settlers there cultivated rice, raised domestic animals, and practiced sophisticated funerary rites. It is also suggested that this area of northeastern Thailand consisted of a network of autonomous villages with no hierarchical sociopolitical order. There is no evidence of a militaristic or violent civilization, with no discovered combat related mortalities. The civilization, however, seems to have vanished around 200 CE.

Nestled between two cultural giants, namely India and China, the historical cultural and social

➤ AN ACCIDENTAL DISCOVERY—THE “LOST” BRONZE AGE

Considering the importance of the archaeological finds of Ban Chiang, it is remarkable that its discovery was purely accidental. A young Harvard student, in July 1966, happened to trip on some tree roots while taking a walk in Ban Chiang. To his and subsequently archaeologist's amazement, he landed face down in some pottery protruding from the earth. The sophistication of their design and artistry quickly drew attention, resulting in the later large-scale excavations. Little did anyone imagine the tools, jewelry, pottery, and human remains that lay beneath these shards of clay.

—Erika Jahn

contributions of the smaller countries of Southeast Asia have been overshadowed. The findings at Non Nok Tha and Ban Chiang, however, contribute to a convincing argument for sedentism and cultural modernization, demonstrating that Southeast Asian civilization was not nearly as primitive as originally presumed.

The Varna Cemetery

The Copper Age cemetery of Varna provides important information about mortuary practices, metallurgy, and the emergence of social ranking in prehistory. The cemetery contains the oldest mass assemblage of gold in the world, and the

➤ WHERE DID THE VARNA GOLD COME FROM?

The Varna gold is of high purity, and chemical analyses have been unable to determine its origin. Although gold is commonly found throughout the Balkans in later periods, the large accumulation at Varna is unique for the Copper Age. It is possible that the population exploited local gold sources that were unavailable to other communities. It is clear, however, that Varna participated in expansive trade networks, and others could theoretically have had access to it. Archaeologists can only guess at the ancient source. Some believe it to be from a combination of local (less than 31 miles, or 50 kilometers) and distant locations. Whatever the case, it is not clear why Varna is the only site to have so much of it.

—Noah V. Honch

early appearance of copper artifacts attests to the independent development of metallurgy in southeastern Europe. The volume and diversity of grave goods at Varna indicate the existence of widespread trade networks in the eastern Balkans and suggest that gold and copper were used to express the social status of deceased individuals.

The Varna cemetery is located in northeastern Bulgaria, slightly inland of the Black Sea and north of the Varna Lakes. Archaeological excavations have uncovered 281 graves, which are typically classified into three groups: (1) inhumations (155 burials), (2) cenotaphs (56 burials), and (3) destroyed burials (70 burials). Inhumations contain full or partial skeletons, which are generally accompanied by grave goods. Cenotaph burials lack human remains but contain significant deposits of diadems, beads, bracelets, and other items that are often placed in anatomical positions on clay masks. Cenotaphs are inferred to be deliberate, symbolic acts of reverence for eminent individuals who are buried elsewhere.

The number and variety of material goods differ considerably between individual graves at Varna. The central core of burials contains exceptionally wealthy inhumations and cenotaphs but lacks the remains of females or children, which may indicate male gender bias. Some burials outside of the core do not contain grave

goods although most do, and females and children are represented. Even though gold appears to be common at Varna, it was used sparingly, particularly in relation to copper, and many objects were made to look as if they were constructed of gold even when they were not. Furthermore, gold was mostly used for decorative and symbolic objects, such as maces and scepters, rather than utilitarian items. And while some burials lacked gold completely, others contained substantial quantities, weighing upwards of 1.5 kilograms. In this light, it appears that gold was highly valued and in all probability was related to the expression of social status in antiquity.

On the whole, however, Varna was an anomaly; no other Copper Age site contained the same amount of gold or showed such marked differences in the distribution of grave goods. Yet Varna was not an isolated populace; to the contrary, many individuals were involved in wide-ranging trade networks. *Dentalium* shells and *Spondylus* bangles are common burial items, both of which are Mediterranean mollusk genera that provide evidence of trade contacts in the Aegean. And while copper sources for the manufacture of artifacts at Varna have not been identified, most Copper Age tools in the Balkans were smelted from ores in south-central Bulgaria, hundreds of kilometers away. Accordingly, although the unique nature of the cemetery remains a mystery, Varna may have been a mortuary center for the interregional elite who played important roles in the formation of alliances and the organization and control of exchange networks in the East Balkans.

European Warrior Graves

European warrior graves began to appear during the Bronze Age, when metallurgical advances and material demands brought forth new means of harnessing and expressing individual power. Warrior graves usually contain a single human and a variety of weapons and armor, such as copper or bronze axes, daggers, projectile points, spears, greaves, helmets, shields, and breastplates. Many graves include pottery connected with ritual feasting, and exotic materials such as amber that originated from distant sources attest to robust trade networks.

The composition of warrior graves varies between geographic regions and time periods. In central Europe, Early Bronze Age warriors were primarily interred in flat graves. By the Middle and Late Bronze Ages, warriors were generally buried in earthen mounds or tumuli that required significant organization and labor to construct, indicating the social importance of those interred. The Leubingen tumulus in Germany, for instance, contained a male warrior with bronze weapons, woodworking tools, and a whetstone for metalworking; similar artifacts at other tumuli suggest that metalworking was an elite skill. Barrow burials in Wessex, England, contain bronze weaponry, sheet goldwork, and foreign materials such as faience and amber, which indicate distant trade contacts in the Mediterranean and the Baltic regions. Unique ship-setting burials in Scandinavia consist of stone slabs in the form of ships. Ship-setting burials signify the importance of boats in trade and raiding; while not restricted to warriors, several burials probably contained leaders and participants of war.

The introduction of the horse and wagon improved mobility during the Bronze Age. Whether horses and wagons were used in warfare or limited to trade and transport, they were expensive to maintain and were likely restricted to the elite. Wagon burials appear in Switzerland, southern Germany, and Austria during the Late Bronze Age and are commonly assumed to be warrior graves. As at Hart an der Alz in southern Bavaria, these burials frequently contain a wagon, a sword, and feasting vessels. Most wagon

Ship burial in Gotland, Sweden. (Jürgen Howaldt)

➤ DID HUMANS IN WARRIOR GRAVES ACTUALLY ENGAGE IN WARFARE?

We often cannot be sure if warriors engaged in warfare. Soft tissues rarely preserve, and battle wounds are difficult to recognize from skeletal evidence. E2 cut marks on bones and weapons occasionally indicate whether an individual fought or died in combat. In rare cases, projectile points are found embedded in bone, suggesting death in battle. Many warriors, however, likely never fought. Countless warrior weapons would have been useless in battle and were symbolic rather than practical. It is likely that some warriors also had the necessary material resources to organize, equip, and control combatants for self-interests without engaging in fighting themselves. Nonetheless, warrior graves are consistently distinguishable from other Bronze Age burials. Whether or not interred individuals engaged in battle, they probably played important social, political, and even religious roles in prehistoric communities.

—Noah V. Honch

burials belong to the Urnfield period, during which individuals were cremated and placed in urns. Although wagons are frequently damaged by cremation and only preserve in part, they are important precursors to Iron Age chariot burials.

Passage Tombs in Ireland

Neolithic peoples in Ireland constructed enormous stone monuments called megaliths that are among Europe's earliest and most impressive prehistoric accomplishments. Many megalithic passage tombs are concentrated along the Boyne River Valley north of Dublin in County Meath. The importance assigned to these tombs for burial of kings and nobles is ascertained by the fact that no regular domestic houses have ever been found from the Neolithic period. They are called passage tombs because of the subterranean passages constructed to hold cremated remains and allow for the passage of people and sunlight.

► PROFESSOR O'KELLY AT NEWGRANGE

Archaeologist Dr. M. J. O'Kelly of University College, Cork, excavated Newgrange between 1962 and 1975 and oversaw the restoration of the white quartz front wall that is visible for miles around. O'Kelly first documented how the center of the passage tomb is illuminated for a brief 17 minutes on the winter solstice because the Neolithic builders cut a special opening above the entrance, intending to send the message that as plant life returns with the summer sun, the deceased Neolithic kings should also live again in some mysterious afterlife. O'Kelly argued for restoration of the white quartz wall in front of Newgrange, giving it a regal and dignified appearance after hundreds of years of being obscured under dirt and sod.

—Jonathan L. Thorndike

This Neolithic passage grave in Newgrange, Ireland, dates to about 3000 BCE. Passage graves were built on mounds of earth and contain multiple chambers connected by subterranean passageways. (Corel)

Among hundreds of Neolithic sites in Ireland, the three most important are the megalithic tombs found at Newgrange, Knowth, and Dowth. Stretched out along a ridge north of the River Boyne, these passage tombs make up a necropolis or megalithic city of the dead similar in purpose to the pyramids of ancient Egypt. Archaeologists date the construction of Ireland's passage tombs to the third millennium BCE, or about 500 years earlier than the pyramids.

Newgrange, the best preserved of the sites, has been associated with the Brugh na Boinne (Palace of the Boyne) in Irish epic poetry such as the "Tain Bo Cualnge" ("The Cattle Raid of Cooley"). The megalithic tomb is 280 feet in diameter and 26 feet in height and was originally enclosed by a circle of standing stones, only a few of which remain. Many stones outside the tomb show intricate abstract carvings in the shape of spirals and diamonds. The exact meaning of these symbols has never been deciphered. At the entrance, visitors stare down a 62-foot-long passage that faces the south, aligned in such a way that on the shortest day of the year (the winter solstice) sunlight moves through the opening above the lintel known as the roof box and down the passage toward the inner chamber. The inner chamber was thought to be a communal burial vault because remains of several individuals were found.

Dr. George Eogan of University College, Dublin, excavated the nearby passage tomb of

Knowth and discovered two opposing passages that are longer in length than those at Newgrange. Still under excavation, Knowth has a large collection of stone carvings and drawings that might eventually yield evidence about the people who built the megalithic tombs. Like Homer's fabled city of Troy, Knowth was occupied by many cultures unrelated to the original builders such as the Bronze Age Beaker People who created metal urns to hold cremated remains, Iron Age Celts, and later Romans, all of whom buried their dead and added on new entrances and buildings. The third passage tomb at Dowth is similar to Newgrange in size and construction technique, but Dowth has been left relatively intact and undisturbed.

Early North American Burial Customs

In North America the early burial customs of prehistoric peoples were highly diverse, changing in complexity across regions and times. Evidence indicates that the majority of burial customs consisted of a variety of simple practices revolving around the interment of individuals until the rise of sedentism and the adoption of agriculture, at which point burial customs became more elaborate and complex. Prior to the elaboration of burial customs at the end of the Archaic period, the archaeological evidence indicates that people practiced relatively simple burial customs that involved specific forms of interment, the adornment of the burial with small material goods (e.g., beads, cloth, red ochre), and the association of certain geophysical phenomena with the dead (e.g., rock cairns, earthen mounds, caves).

For example, in Lyon's Ferry, Washington, the Marmes Rockshelter is one of the earliest

known burial sites for the Pacific Northwest. Dating to 6,500–4,000 years before the present, burials from the site contained skeletal material, beads, and evidence of red ochre use. One burial contained approximately 80 olivella shell beads and large amounts of red ochre, while another burial was of an individual of unknown gender between the ages of six and eight who was buried with three antler shafts, olivella beads, and red ochre. Other burials from the site appear to have been specifically oriented toward the east, and stone artifacts and rock cairns were also associated with some of the burials.

Nearby at the DeMoss Site in Idaho, a burial site was discovered containing the remains of at least 22 individuals of all ages along with 236 burial blades, cascade points, and side-notched points. The burials contained bifacial cache blades, large side-notched projectile points, obsidian preforms (pieces of obsidian that have not yet been fully knapped into tools), and Olivella shell beads. Evidence also indicates that the bodies may have been ritually cremated as part of the burial custom. As Sprague has argued for the region as a whole, these burial customs can be traced back to the initial peopling of the area.

To the south in the Great Basin region, slightly different burial customs seem to have been practiced, although the use of beads and red ochre were ubiquitous. Studies of the burial patterns in the Great Basin have led some to conclude that the pattern extends over a long period of time, with an emphasis on inhumation especially in rocky areas and the infrequent but regular use of cremation. For example, early Great Basin burial customs show a strong preference for burial in rocks or rocky places with the body wrapped and extended, with areas of cremation, such as in the western California regions of Owens Valley and Death Valley. Orientation of skulls shows a weak pattern of westerly preference in the north, an easterly preference in the south, and a variable preference in the central region. However, some have countered this general conclusion by noting that at some important sites, no pattern over time can be found. For example, at Lovelock Cave in Nevada, no clear burial custom across time has been determined. Burials from the site evidence a female oriented west; a flexed child oriented southwest; an infant

► BURIAL CUSTOMS AT LOVELOCK CAVE

Lovelock Cave is an open rock shelter located in western Nevada. Human use of the rock shelter began around 3000 BCE and continued into the historic period. Throughout this long period of use, evidence indicates that the interior of the rock shelter was used only for burials and storage; all evidence of domestic activities are from the outside rim of the rock shelter. Overall, more than 20,000 artifacts and faunal remains have been recovered along with at least 75 human burials that evidence social complexity and a developed burial practice.

For example, one skeleton of a 35-year-old male lay in a semiflexed position on its left side with the head oriented west and facing north. The grave goods were recovered from the ventral side of the skeleton near the ribs and included 24 shell beads and ornaments, 9 ground stone objects, 6 bone artifacts, and 1 chipped stone point. The presence of Pacific Ocean beads evidences long-distance trade and exchange with other groups.

—Peter N. Jones

oriented northwest; an adult flexed on the left side and oriented northeast; a cremated skeleton of unknown age, flexed on the back, oriented west and with stones over it; a cremated child; a cremated infant; and a male adult flexed on the left side and oriented west. Furthermore, some of these burials evidence the use of sagebrush to line the burial pit as well as to cover it after the individual had been deposited. Other burials from the Great Basin indicate that wrapping the body in woven material and covering the head with oval-shaped rocks was also common, as was placing the body in extended to semiflexed positions. Some burials appear to show signs of a division in social ranking, as some burials from the region have yielded artifacts made from Pacific Ocean marine shells.

In the Plains region, early burial customs appear to have also been fairly similar. For example, a Middle Archaic burial from the Plains-Prairie border in East-central Kansas contained deer bone, a drill, and a side-notched projectile

point or knife. Use-wear analysis demonstrates that the stone tools were used before being placed with the burial and therefore were not manufactured specifically as burial goods. Dating to 6,000 years before the present, this burial compared to other burials from the region shows similarities in burial customs across the Plains. In the Northeast and Southeast, evidence indicates that burial customs became more elaborate and complex at an earlier date than in the rest of North America, with the appearance of large earthen burial mounds by the Late Archaic (5,950–4,450 years before the present). Architectural structures were also associated with burial customs in the Southwest although not until sedentism arose in the region between 3,000 and 1,500 years before the present.

Migration and Travel

Around 3300 BCE, high up on the Similaun Mountain in the Alps, Oetzi (a name given him by modern researchers) collapsed from the wound he had received a few minutes earlier. He had pulled the shaft of an arrow out of the back of his shoulder but had not been able to dislodge the arrowhead. Having eaten his last meal about eight hours previously, Oetzi had probably set off from a village downslope with companions but had gotten involved in a fatal skirmish. After Oetzi passed on, his body was covered by the Schnalstal Glacier, not to be revealed again until 1991, when two German tourists discovered him, an extremely well-preserved example of a human from the Copper Age whose travel plans had ended abruptly.

Not all travel in this period was as fraught with peril as Oetzi's travels. The period 4000–1000 BCE was a period in which technologies and networks necessary for travel developed to allow people to move across substantial distances and environmental divides relatively easily and safely. The ease with which people could now travel led to the development of different travel motivations. More complex nautical skills made long-distance trade more viable. The development of the wheeled cart, pulled by oxen, allowed people to travel with more than what they could carry on their backs. People could also easily return to their homeland after a long voyage, allowing for travel as opposed to merely migration.

Yet there were still some major migrations between 4000 and 1000 BCE. In some cases, there is much evidence for migration but little evidence to explain why the migration occurred. The Sea Peoples, for example, were a coalition of different groups from Greece, Libya, and perhaps elsewhere. They traveled from these regions and attacked Anatolia, and some of them settled on the coast of what is now Israel. Why they abandoned their homeland for this new region is debated by archaeologists, but the fact that they did so is not. In other cases, there are historical or religious accounts of migration, but the archaeological evidence does not corroborate these accounts. The Israelite exodus from Egypt and the Aryan invasion of India are both important subjects in the sacred literature of modern political and faith communities. Yet positive archaeological evidence for either of these migrations is profoundly lacking. Making sense of these discrepancies is one of the challenges archaeologists face in reconstructing world history from 4000 to 1000 BCE.

Archaeological exploration in central Asia has shown that the history of travel and migration between Europe and East Asia is much more complex than what has been previously assumed. Excavations in the Tarim Basin in Turfan have unearthed bodies that bear a closer

physical resemblance to what one would expect from European populations at this time as opposed to East Asian. The presence of this population, who may have spoken an Indo-European language, this far east has shown that the boundary between Europe and Asia was fluid, even in this early period.

Since this is the period of the earliest writing, this is also the first period of travel writing. Accounts of voyages to distant lands are thrilling, and no doubt these first attempts at the genre were exciting to ancient audiences. The ancient Egyptians, who had a strong sense of Egyptian identity and truly felt that Egyptian civilization was normative and that all other civilizations were aberrations of this norm, produced

One set of inscriptions, carved on the walls of Queen Hatshepsut's funerary monument at Deir el-Bahari, provide our only evidence for the yet-to-be-identified African kingdom of Punt. Who knows what other civilizations may have existed in this period that we do not yet know about?

some of the most fascinating accounts of journeys to foreign lands. One set of inscriptions, carved on the walls of Queen Hatshepsut's funerary monument at Deir el-Bahari, provide our only evidence for the yet-to-be-identified African kingdom of Punt. Who knows what other civilizations may have existed in this period that we do not yet know about?

As you read the following entries about travel and migration from 4000 to 1000 BCE, you may notice a methodological tension of sorts. Archaeologists can be

uncomfortable discussing the movement of people, since what they usually have evidence for is the movement of artifacts. In the early twentieth century, archaeologists used the model of migration to account for all change. Any time a new type of artifact appeared or house styles changed, scholars postulated that a new group had moved in and settled in the region. In the 1960s and 1970s, migration as a means of explaining change fell out of vogue, and archaeologists went out of their way to explain any changes as having been caused by anything but migration! The pendulum has swung back to somewhere in the middle ground now. Archaeologists acknowledge that change can be caused by the migration of people but that this is not the only mechanism of change.

—Kevin M. McGeough

■ Introduction: Strangers in a Strange Land—Ancient Travelers

While there was a great deal of travel throughout the age between 4000 and 1000 BCE, there are some unique examples of particularly brave (or foolhardy) travelers who ventured outside of their home

territory into far-off lands. There was an established infrastructure for traveling traders and for state-sponsored expeditions (which will be explored more fully throughout the rest of Theme 3 of this volume), and there certainly are many

examples of large-scale population migrations during this time. Yet there are also hints of individuals who traveled outside of established trade routes, some such as Oetzi the Iceman and the Urumqi mummies dying before they returned to their homelands.

What inspired these ancient travelers to set out for far-off lands? In the case of the Bronze Age traders and the Medjay police force in Egypt, economic and sociopolitical opportunities were motivation enough. But what about the lone travelers who wandered farther than they could possibly return from? Were they lost? Were they in some sort of legal trouble or fleeing their homelands for other reasons? Did warfare leave them isolated and without a community? Or were they merely curious, tourists before the tourism industry? Unfortunately, when archaeological remains are all that are left of these ancient travelers, historians can only make educated guesses about what may have motivated them.

It can often be difficult to identify the remains of ancient travelers, who did not leave textual records of their journeys. In the case of the Iceman, it was clear that he was traveling since he was found in an inhospitable part of the Alps. Likewise, the Urumqi mummies appear to have come from elsewhere, given that they share physical characteristics that differentiate them from the local population. It is possible that there are many more ancient travelers who have not been identified as such, since markers of difference may not have survived from antiquity. These isolated cases that have been identified point to the possibility that there may have been significantly more travel than scholars can identify.

—Kevin M. McGeough

Oetzi the Iceman

Oetzi is a naturally preserved Copper Age mummy that was discovered in the alpine region between Austria and Italy in 1991. He is named after the Ötztal Valley, near the location of his discovery, but is also referred to as the “Iceman,” the “Similaun Man,” and “the man from Hauslabjoch.” Oetzi’s body was found in a protective rock hallow that contained a variety of tools, weapons, and clothing, many of which were made from materials that rarely preserve in the

The body of Oetzi the Iceman found in Italy's Ötztal Alps (near present-day Austria) in 1991. Oetzi died around 3300 BCE. (Corbis)

archaeological record. These objects provide important information about Oetzi but also offer insight into the prehistoric time in which he lived. Although Oetzi and his belongings have been the focus of intensive research, pervasive questions remain about his identity, his place of origin, and the circumstances behind his death.

Oetzi was initially discovered by passing hikers, who noticed the human corpse partially entrenched in glacial ice and melt water. After two recovery attempts, the corpse was removed and transported by a forensic specialist to the University of Innsbruck, Austria, where it was examined and recorded. Preliminary investigations of Oetzi's tissues revealed that the cold, dry conditions of the glacial environment had mummified his body. Consequently, protective measures were taken to prevent exposure to contamination and inhibit the thawing of tissues. Subsequent tooth wear studies and computed tomography (CT) scans of Oetzi's skull suggested that he was between 25 and 40 years of age at the time of death.

A preliminary assessment of the recovered artifacts suggested that Oetzi dated to the Bronze Age. Radiocarbon dates of Oetzi's tissues, however, indicated that he was older and probably lived during the Copper Age, around 3300 BC. Metallurgical studies of Oetzi's axe, which was hafted in wood and bound with leather, determined that it was made of copper, not bronze, and thus confirmed the Copper Age date.

► THE INTERNATIONAL BATTLE FOR OETZI

Oetzi was found on an alpine ridge in Tyrol, a region that straddles the border between Austria and Italy. During the early twentieth century, Tyrol was united under the Austrian-Habsburg empire. After World War I, however, the border between these countries was redrawn, and South Tyrol was given to Italy, effectively cutting some German-speaking populations out of Austria. The border has been contentious ever since. Although Oetzi was brought to Austria after his recovery, it was known that he may actually have been discovered in Italy. As Oetzi's story became high profile, so too did interest in his ownership. Did he belong to Italy or Austria? Existing maps suggested that Oetzi was found in Austria. A subsequent trek by government surveyors from both countries determined that the body was found in Italy. South Tyrol, however, did not have a university or the appropriate facilities to ensure Oetzi's preservation, complicating his return to Italy. The larger scientific community realized that Oetzi did not just belong to Austria or Italy but instead belonged to everyone and that his conservation was of utmost importance. At the same time, however, they respected Italy's claim to a find that could bolster tourism. In 1992, after significant deliberations, a treaty was signed between Italy and Austria that allowed Oetzi to remain at the University of Innsbruck for research but ultimately called for his return to Italy when appropriate storage facilities were in place. In 1998, Oetzi was transferred to Bolzano, Italy, where he remains on display in an environmentally controlled chamber in the South Tyrol Museum of Archaeology.

—Noah V. Honch

Oetzi may have made the axe himself. Chemical analyses have discovered arsenic within the physical structure of his hair, which was probably ingested during the smelting of arsenical copper ores.

Oetzi's belongings were constructed from a variety of materials and suggest that he had extensive knowledge of the natural world. His clothing was largely made from the skins of hunted animals and included deerskin leggings, a goatskin loincloth, a hat with bear fur, and

shoes that contained deerskin, calfskin, and grass insulation. Oetzi also had a deerskin coat and a long grass cape that was likely worn on the outside. He possessed a bow of yew wood, which is naturally flexible and conducive to bow making, and 14 unfinished arrows of viburnum and dogwood, two of which had flint projectile points and feathered fletching. The arrowheads show evidence of retouching and were probably worked by Oetzi with an antler fragment that was hafted into wood and found near his body.

Oetzi was almost certainly a seasoned traveler. In one of two birch bark containers, he carried rolled-up maple leaves that held embers that could be transported and used to ignite fires. CT scans of Oetzi's body suggest that he suffered from arthritis and showed evidence of biomechanical adaptations (e.g., well-developed nutrient canals and thick cortices in his lower leg bones) that were probably related to extensive walking in mountainous valleys. Tattoos on Oetzi's lower back, legs, and feet are aligned with important acupuncture points and, if not for aesthetic value, may have marked places to relieve stress.

In many ways it is not certain who Oetzi was, where he lived, and why he was found so high in the Alps. It has been suggested that he was everything from a herder to a hunter, a shaman, a warrior, a metal smith, or a trader. If Oetzi herded sheep or goats, he likely also hunted or traded, since much of his clothing was made from animal skins and furs. Although his belongings appear to be too practical for a shaman, it is possible that Oetzi was familiar with metallurgy and used rituals to guide his work. The diversity of other materials and evidence for travel, however, imply that he did not specialize in metallurgy alone and may have been involved in a number of socioeconomic spheres.

The remote location of Oetzi's death makes it difficult to connect him to local Copper Age sites. Oetzi's colon and stomach contents contained einkorn wheat, a domesticated cereal that indicates he was in contact with or part of a sedentary agricultural community. It has been suggested that Oetzi belonged to a village that farmed poor alpine soils and supplemented their diets with animal products from wild and domesticated species. Unfortunately, there is little

archaeological evidence for such communities. Local cultural relationships cannot be traced with pottery because Oetzi was not found to carry any. Oetzi's flanged axe is similar to one found at the prehistoric cemetery of Remedello Sotto, leading some to believe that he lived south of the Alps. The archaeological relationship is weak, however, since there are 119 graves at Remedello, and the axe is the only item of like comparison. On the other side of the Alps, several villages are known to have statue menhirs, carved stones that depict humans engaging in a variety of activities. Some menhirs portray humans with flanged axes, which may represent the small proportion of humans actually buried with such weapons. Oetzi's axe is similar to these depictions and suggests that he may have been an important figure in his community, wherever it may have been.

The circumstances behind Oetzi's death remain unclear. Early theories suggested a fight-and-flight scenario whereby Oetzi engaged in a violent confrontation, was wounded, and fled to the mountains where he died. Others believed that Oetzi died from exhaustion while traveling, that he was caught in a storm and froze to death. CT scans recently discovered a flint projectile point in Oetzi's left shoulder that would have entered from the back. Although it missed vital organs, the arrowhead almost certainly caused heavy bleeding, inevitably resulting in Oetzi's death. How and why he was shot, however, remains a mystery. It might not ever be clear whether he died in combat, was intentionally murdered, or was simply the victim of a hunting accident.

The Urumqi Mummies

The Urumqi mummies are a group of remarkably well-preserved humans from the desert environment of the Tarim Basin in western China (Xinjiang Province). Although the mummies date to the late second and first millennia BCE, they are virtually all caucasoid. They are tall; their hair is brown, red, or blonde; and their eye sockets are typically large and round. Their clothing is mainly woven from sheep wool but frequently consists of animal skins and furs, which provide vital information about early textile technologies, the environment, ancient aesthetics, and human migrations in central Asia.

The Tarim Basin is conducive to natural processes of mummification. The long winters and dry summers inhibit tissue degradation, and the salty desert sands draw moisture from the body. Evidence suggests, however, that mummification was a deliberate cultural practice in this region. Numerous mummies were covered in a protein paste, which may have acted as a preservative, or were placed on wooden platforms to enhance air circulation and the desiccation of soft tissues. Several mummies were also buried in wood-lined coffins or under hollowed-out logs, which exposed their bodies to the desert sands.

The most important information about the Urumqi mummies is derived from preserved textiles. Most of the mummies wore heavy insulated clothing. The well-known Cherchen Man, for instance, wore deerskin boots, felt leggings, woollen pants, and a shirt. The Beauty of Loulan, a famous female mummy, was clothed in a long, thick garment of wool and fur and had moccasins on her feet. The necessity of insulated

Urumqi mummy from the Tarim Basin in western China, late second–first millennium BCE. (Reza/Webistan/Corbis)

► THE LEGACY OF THE URUMQI MUMMIES

Early Chinese writings describe encounters with Yeuzhi or Ruzhi peoples, unusually tall people with full beards, bright eyes, and light hair. It is widely believed that these Yeuzhi or Ruzhi spoke Tocharian, an Indo-European language whose earliest writings date to the first millennium CE. Tocharian has astonishing linguistic similarities to the Celtic and Italic languages of western Europe, much like the stylistic similarities of textiles between the Urumqi mummies and prehistoric Celtic societies. Although the Urumqi mummies lived well before the first millennium CE, they may have been influential in shaping the linguistic and genetic fabric of populations in the Tarim Basin, which eventually gave rise to the Tocharians.

—Noah V. Honch

clothing indicates that winter conditions were difficult in the Tarim Basin and often resulted in death. Sheep wool was commonly used to manufacture suitable clothing, suggesting that local humans engaged in animal herding that probably complemented small-scale agricultural practices during the warmer months.

Many garments on the mummies show evidence of twill weaving, a technique that was virtually absent in China until the Western Han period (206 BCE–25 CE) and was probably introduced from the West. The clothing designs of the Urumqi mummies frequently include tartans and plaid striping, which resemble the patterns of preserved textiles from the Bronze and Iron Age salt mines of Hallstatt, Austria. Although textiles rarely preserve, there is sufficient evidence to indicate that tartans were common in Celtic societies throughout Europe. In light of stylistic influences in textile design and the overt caucasoid physical features of the mummies, the Urumqi mummies provide evidence of early human migrations between the steppe environment of eastern Europe and the relatively unoccupied marginal regions of central Asia during the late second and early first millennia BCE.

The major impetus for early migrations between eastern Europe and central Asia is unknown. It is possible that migrants from the Caucasus were involved in the silk trade and

may have been responsible for the regional introduction of the chariot by the second millennium BCE. It is apparent, however, that the earliest Urumqi mummies date to approximately 2000 BCE, well before the nomadic era of the horse, and this suggests that migrants were initially involved in small-scale agriculture and animal herding.

The Medjay—Nubian Police in Egypt

Although the ancient Egyptians often took an outwardly xenophobic or foreign-hating stance toward non-Egyptians, the Medjay (also Medjayu) illustrate that such sentiments did not prevent Egypt from capitalizing on advantageous relationships. Attested from the Old Kingdom onward, the Egyptian term "Medjay" initially referred to nomadic and seminomadic tribal groups of the eastern desert regions of Nubia. Keeping a predominantly pastoral lifestyle with a focus on cattle, their seasonal migrations in search of hospitable grazing lands moved them primarily along the Red Sea coast and neighboring hill regions east of northern Nubia (modern Sudan). Their travels also brought them within Egypt's borders to the north and into contact with other Nubian groups closer to the Nile.

Much of what is known about the Medjay is derived from ancient Egyptian textual and pictorial sources and thus represents a distinctly Egyptian view. The Medjay are represented archaeologically within Egypt by remains of the Pan-Grave group with whom they are customarily equated. Although generally somewhat dispersed, by the Middle Kingdom the Medjay were organized enough in two territories to be regarded by Egypt in essentially the same manner as larger, more consolidated foreign polities.

During periods of Egyptian exploitation of natural resources in the Nubian desert, conflict

with Medjay groups was still common. Egypt employed both practical and magical measures against such threatening segments of the Nubian population. One of many Egyptian military forts established in Nubia during the Middle Kingdom received the unambiguous symbolic name of That-which-Repels-the-Medjay (or simply Repeller-of-the-Medjay). The Medjay are also targeted among Egypt's traditional enemies in Execration Texts, ritual writings intended to magically neutralize dangerous forces whose interests ran contrary to those of Egypt.

Yet the most threatening aspects of the Medjay could also be co-opted by the Egyptians as useful assets. They became renowned for their aptitude at desert tracking and warfare. Nubians in particular were known as highly skilled bowmen. By the Late Old Kingdom into the First Intermediate period, Medjay were already finding positions in Egyptian military service, although they appear most active as mercenaries in later sources dating to the Middle and New Kingdoms. They were even included among forces employed at Egyptian forts in Nubia, established in part to control the movements of the indigenous population.

A widely acknowledged tactical role eventually prompted the word "Medjay" to shed its

➤ THE MEDJAY IN THE SERVICE OF KAMOSE

The Medjay feature prominently in accounts of Dynasty seventeen military efforts late in the Second Intermediate period. Kamose, last king of this Theban dynasty, found himself in an ominous position between two hostile powers: the Canaanite Hyksos in northern Egypt and their Nubian allies, the Kushites, wielding power to the south. In a northward push against the Hyksos, Medjay archers were employed as scouts and watchmen, roles of paramount importance under the circumstances. It was likely that these forces intercepted an envoy with a dispatch from the Hyksos king Apophis to his Nubian ally at Kush, severing communication between the two. Despite Kamose's favorable account of his battles, it was left to his successor Ahmose to regain Egypt under Dynasty eighteen and inaugurate the New Kingdom.

—Nicholas S. Picardo

specificity of meaning during the New Kingdom. Losing its cultural association with Nubia, the term came to refer to protective agents who acted much like a standing police force. The responsibilities of these troops included security patrols along the desert margins, guard duty in necropolises, and more specific duties such as participating in the investigation of tomb robberies in the Valley of the Kings.

■ Introduction: Migration Mysteries

The origins of many groups are dated to the time between 4000 and 1000 BCE. Yet these origins are often quite obscure, preserved only in mythical accounts or vague recollections. Historians have a number of tools that can be used to reconstruct ancient movements and deconstruct the biases that are intrinsic to migration stories in order to solve these migration mysteries. The safest proof of movement comes from the study of material culture, which is discussed in depth in the next section. Biases are often apparent in textual or oral accounts of migrations, but historians can often identify these biases and come to conclusions about the historical realities behind these tales by comparing these accounts with other types of evidence.

Linguistics can also provide important evidence, although most historians are not trained in historical or comparative linguistics and thus are less likely to use this kind of evidence. Language from the age can be preserved in ancient writing and often in the language of modern inhabitants of the region. Linguists argue that changes in language are not arbitrary, but changes follow typical patterns under particular sets of circumstances. Tracing changes through time and deducing possible causes for the changes may allow scholars to reconstruct ancient movement from the idiosyncrasies of a modern speech community. The easiest way that language can be used to understand ancient migration, however, is when scholars can identify that a new language was introduced into the region. Often it is possible to identify where that language (or related language) was spoken previously and thus reconstruct that a group of speakers of that language moved to the new region.

The work of historians is more complicated by the fact that accounts of ancient migration can be incredibly politically loaded in the present. A story of a group's origins is often burdened by the political and social issues of the present, and often these kinds of stories are manipulated for political purposes in the present. As in the case of the origins of the Zhou dynasty, various communities are proud of what they see

as their region's contributions to history and their own connections to these glorious ancestors. Other times, such as in modern-day India and Pakistan, the supposed movements of people 4,000 years ago have a bearing on political actions taken in the present.

Bantu Expansions, Earliest Times to circa 1000 BCE

From early in the history of contact between African peoples and travelers to the continent, visitors have remarked on the surprising similarity between many of the languages spoken in central, East, and southern Africa. Indeed, about a third of the languages spoken in Africa today are of the same family of languages. How did so many African people come to speak related languages over such a huge expanse of the continent?

Scholars trying to answer this question used the word “Bantu” (literally “people”) to refer to the related family of languages, the peoples who speak those languages, and the cultures they share. Yet each of these ideas—the Bantu languages, the Bantu people, and Bantu culture—carries very different assumptions about the history of the expansion of the Bantu languages across central, East, and southern Africa.

To refer to the Bantu as a group of people could imply that all Bantu people are genetically related to each other or that they form a racially distinct people, neither of which is the case. Or, we could assume that the Bantu people share a political relationship like the British, all of whom are citizens of the United Kingdom. Yet speakers of Bantu languages today and in the past belonged to hundreds of distinct polities, from great kingdoms to smaller-scale neighborhoods. Moreover, when we speak of a common Bantu culture, we risk losing sight of the diversity of lifeways that speakers of Bantu languages developed over the last several thousand years, from the Bambenga-speaking hunting and foraging specialists of the equatorial rain forests to the ChiTonga-speaking farmers of the southern sa-

vannas to the Kiswahili-speaking traders of the coast of East Africa.

To speak about the history of the Bantu Expansions, then, is to talk about the history of a group of people bound together by a shared linguistic history rather than a shared geographic or political history, as we might study with Native American or British history. This shared linguistic heritage tells us something of the history of peoples speaking Bantu languages because scholars can reconstruct the words used to talk about the things and ideas that constituted the world of people living long ago and speaking languages of the Bantu family. That is to say, tracing the history of the development of Bantu

words allows us to trace the history of the experience of people speaking Bantu languages.

All Bantu languages share a single ancestral language, Proto-Bantu. The history of Bantu-speaking peoples, then, begins in the border region between modern-day Nigeria and Cameroon, where Proto-Bantu was first spoken 5,000 to 7,000 years ago. The earliest speakers of Bantu languages, speakers of Proto-Bantu, cut out small gardens from the forests and farmed root crops such as yams and groundnuts (similar to peanuts) as well as beans, peas, and gourds. They tended wild oil and raphia palm trees for cooking oil and fibers for weaving mats and baskets. They kept goats, dogs, and guinea fowl. They

also hunted, fished, and gathered wild foods and medicines from the niches of the swampy, grassy, and woody lands of the diverse rain forest environment.

Early Bantu speakers were probably organized around prominent charismatic leaders who attracted followers by composing successful communities, communities with skilled healers and priests and enough people to provide food for the young and the old. With a plethora of land and a relative scarcity of people, leaders had to work hard to attract followers, because those who felt that their needs were not met by their leaders could “vote with their feet” and either start or join a new settlement. While scholars are not sure if formalized organization into patrilineages and matrilineages existed in the earliest eras of Bantu history, real and fictive family ties played an important role in helping people organize their relationships with each other.

For example, early Bantu communities of the equatorial rain forests organized themselves into Houses led by Big Men (charismatic wealthy leaders), whose power was justified by their role as the supposed “father” of all the members of the House. Houses cooperated with each other and collected into villages that could, in turn, cooperate as a district-wide collection of villages. Some Houses developed alliances with Houses in different villages, creating clans. Houses could vary in size from a large family with a few hangers-on to several hundred people, all working together to ensure that the group was fed, that ancestors and spirits were happy, that youths matured into adulthood, and that the House grew in wealth and prominence.

Early scholarship on the Bantu Expansions explained the spread of Bantu languages using concepts such as mass migration, military conquest, and technological superiority, concepts that better reflected Europeans’ own ideas about their role as colonizers. Scholars now believe that the Bantu languages slowly spread east and south through two simultaneous processes. Farmers spread out, searching for new places to plant their yam crops when soils were exhausted or to found new settlements when Houses or villages grew too large. At the same time, the demographic advantages of farming and sedentism that

allowed speakers of Bantu languages to live in bigger settlements than mobile hunter-gatherers may have produced a situation in which Bantu languages served as a lingua franca in trade negotiations or as a regional language of prestige. Speakers of non-Bantu languages slowly adopted Bantu languages, contributing to the spread of those languages.

Bantu speakers interacted frequently with autochthonous hunter-foragers living in the lands into which Bantu speakers moved. Autochthonous people were an important source of information about local resources and a vital ritual link to the spirits of the land and of the ancestors. Indeed, Bantu speakers probably sought to attract notable spirit mediums whose ability to communicate with the spirit world made them important intercessors between unfamiliar spirits and immigrant Bantu speakers. Bantu speakers’ social organization was flexible and incorporative; non-Bantu peoples were easily absorbed into Houses through ties of kinship, dependence, and friendship. These new members helped Bantu immigrants to successfully propitiate the ancestors and learn about local forest resources such as honey and medicines. Bantu speakers taught autochthonous peoples about their novel social organization and technologies such as farming.

Just as the actions of people caused Bantu languages to spread across the rain forests, they also contributed to the emergence of new generations of languages in the Bantu family tree. Each ancestral language, starting with Proto-Bantu, slowly diverged into new daughter languages. Sounds changed and vocabulary was replaced in the ancestral language until speakers on distant ends of the geographic expanse in which the ancestral language was spoken could no longer understand each other. They now spoke such different versions of the original ancestral language that they no longer spoke dialects of that language but rather new distinct languages, the next generation of the Bantu language family tree.

Over several thousand years, through the movement of people and the adoption of Bantu languages, the lands in which Bantu languages were spoken grew, extending southward through the forests of modern-day southern Cameroon and along the Atlantic coast of modern-day Ga-

bon. In the rain forests, an extensive system of waterways may have accelerated the spread of people and languages into the interior and eastern regions, with rivers serving as a highway system that facilitated transportation and communication. By 1000 BCE, people spoke Bantu languages in the Bantu homeland on the border of Nigeria and Cameroon and as far south as the central Africa savannas in the modern-day southern Democratic Republic of the Congo, as far west as the Atlantic Ocean of west-central Africa, and as far east as the fringes of the rain forest on the edge of the Great Lakes Region as well as all the lands between those frontiers. During the last 3,000 years, speakers of Bantu languages would continue to spread east and south, drawing on both their shared cultural heritage and their capacity to innovate new ways of making a living, of composing successful communities, and of appeasing the ancestors as they faced the opportunities and challenges of technological innovation, climate change, and contact with new neighbors.

The Dorian Migration—The Mythical Migration of the Children of Heracles

The Dorian invasion refers to the movement of peoples ca. 1200 BCE from the north of Greece into the Peloponnesus, a Greek peninsula that extends south into the Mediterranean Sea. That migration, which is also called the Return of the Heraclids, has been considered by some scholars to be responsible for the destruction of the Mycenaean world.

According to myth, the sons of Heracles were expelled from the Peloponnesus by Eurystheus.

After an unsuccessful attempt to come back, they settled in central Greece until the Oracle at Delphi informed them that the time had come for their return, whereupon they were divided into three groups, descended to the Peloponnesus, and conquered most parts of it. Another version of the legend has them wandering until reaching Doris, a small region in the mountains of central Greece, where they settled on land given by the king, thus establishing a friendship with the Dorian people, who would later help them invade the Peloponnesus. According to others and ignoring the myth, Doris was erroneously thought to be the Dorians' original homeland, but rather they emerged from Epirus in northwestern Greece and migrated south.

None of the ancient writers ever suggested that the Dorian migration was a destructive affair, and it was only after German archaeologist Heinrich Schliemann's excavations in the nineteenth century that the picture changed. Schliemann found that the Mycenaean centers were suddenly and catastrophically destroyed, most probably by human hands, and immediately the Dorians were held responsible. Thus, in the nineteenth century, the Dorian migration became known as the Dorian invasion, and its date was synchronized with the fall of Mycenae, sometime between the end of the thirteenth and the end of the twelfth century BCE.

The argument that a new population entered the Peloponnesus mostly comes from the later appearance of the Doric dialect. In terms of archaeological evidence, the invasion of a foreign people can be attested by the appearance of new metal types: the bronze flange-hilted sword with a straight blade known as the Griffzungenschwert sword; the spearhead with flame-shaped blade and a complete cast socket; a type of flange-hilted dagger called the Peschiera dagger; a single-edged knife, with or without a curved blade; a type of lugged ax called the Armchenbeil; and the so-called violin-bow fibula (clasp), which was related to the use of thicker clothes.

However, the evidence so far does not support the theory of an invasion, and most scholars no longer accept that explanation. There is no distinctive material culture that would define the invaders, and most of what were thought to be new metal types actually appeared long before

the destruction. In addition, the destruction in the Mycenaean world occurred over quite a long period and according to no geographical pattern that would imply an invasion. Innovations in burial practices (namely the frequent use of cyst graves) could imply the arrival of a new population, but they appeared well after the destruction of the Mycenaean world. Therefore, there is a possibility that the so-called Dorian invasion was actually an infiltration of peoples into a half-empty land, and not a military invasion.

Heinrich Schliemann's Theories of Ancient Greek Invasions

Although Heinrich Schliemann was an amateur archaeologist, his excavations in Asia Minor at Troy changed our knowledge of early Greece

➤ SCHLIEMANN EXCAVATES IN MYCENAE

Heinrich Schliemann went to Mycenae in 1876 because Homer described the city as “rich in gold,” and the archaeologist unearthed specimens that were hair-width thin and expertly crafted. A golden goblet was named by Schliemann “the cup of Nestor” along with the gold funeral mask he named the “Mask of Agamemnon.” Schliemann liked to think that he had exhumed the very corpse of the warrior-king who led the Greek invasion. He supposedly wrote a telegram with the breathless line, “Today I have gazed upon the face of Agamemnon bold.” Many scholars doubt that Schliemann ever wrote this, but the line accurately describes his enthusiasm and the importance of his discovery.

—Jonathan L. Thorndike

German archaeologist
Heinrich Schliemann.
(Library of Congress)

and origins of the Trojan War. Before Schliemann, knowledge of the Greek Bronze Age was only conjectural. Schliemann has been accused of overzealous romanticism, but the sheer number of objects he unearthed rank him among the giants in archaeology. Even if he exaggerated his finds, his excavations made an enormous contribution to

our understanding of Greek culture.

Schliemann was born in 1822 in eastern Germany. His father was a Lutheran pastor who fueled his son's imagination with heroic stories of the Trojan War. When Schliemann saw a picture of Aeneas escaping from the burning city of Troy, he said that he would one day excavate the city. He wrote in his autobiography that he had an “obsession” with discovering a historical basis for Homer's *Iliad*. Ilios is the alternate name for Troy, the powerful fortified city in northwestern Asia Minor (Anatolia) where, according to Greek myth, Paris ran off with Helen, wife of Menelaus. Troy is located near the Dardanelles Straits at a crossroads on the major waterway connecting the Mediterranean Sea and the Black Sea.

Beginning in 1870, Schliemann began excavating on a hill next to the mouth of the Dardanelles in present-day Hissarlik, Turkey. He found the ruins of nine cities built on top of each other that were complete with pots, weapons, and a jewelry hoard he labeled the Treasure of Priam. When news of his discoveries reached newspapers in Europe and America, Schliemann became an overnight celebrity.

Schliemann was convinced that Hissarlik was the site of Homer's legendary walled city of Troy. Subsequent excavations led by Schliemann's colleague Wilhelm Dorpfeld in 1890 and by Americans William Semple and Carl Blegen from 1932 to 1938 revealed that Troy was a major city throughout the third and second millennia BCE. Archaeologists designated the nine layers at Troy

from earliest to latest with the Roman numerals I through IX.

On the level of Troy VII, Schliemann found traces of a fire that destroyed the city in the thirteenth century BCE. He thought that Mycenaean Greek invaders whose famous deeds were recounted by Homer probably started the fire. In the *Iliad*, a loose confederation of Greek warriors led by Agamemnon seeks revenge on Troy for the theft of Helen, wife of Agamemnon's brother Menelaus. However, an invasion by Mycenaeans against Troy would be more likely based on Troy's political, military, and economic power as a major regulator of trade rather than on the abduction of one person. Archaeology on sunken ships has confirmed extensive commercial traffic and the existence of imported precious metals, pottery, amber, and grain at many Aegean sites. If Troy stood at a crossroads between east and west, it might have taxed shipping and regulated traffic, giving Greeks incentive to invade and destroy the famous walled city. Modern excavations at Troy show that Schliemann was wrong about the dating of Troy, which he assumed to be of the Mycenaean era or the late Bronze Age (1600–1000 BCE). The Treasure of Priam and other relics actually date to about 2500 BCE, or 600–1,000 years earlier than the rise of Mycenaean civilization in Greece.

Theories of the Origins of the Indo-Europeans

“Indo-Europeans” is a generic term referring to those people in antiquity who spoke languages that stem from a common ancestral source. The close relationship between many of the languages of southern Asia and most of the languages of Europe has been known for more than 200 years. The first to speak about Indic-European

languages was Franz Bopp in his comparative grammar that sparked Indo-European studies, published in 1816. The most remote of these languages in the south is Singhala in Sri Lanka, and the northernmost in Europe is Icelandic.

Some 410 languages are spoken in the world today for which a common ancestral language, Proto-Indo-European, has been reconstructed. The beginning of the formative period of that earliest variety of Indo-European dates back to circa 7000 BCE. It has become customary to call the people who spoke that protolanguage, and other ancient languages derived from it, Indo-Europeans. The homeland of the Indo-Europeans has been a matter of dispute up to the present. The origins of the Indo-Europeans have been sought in Europe, Asia, and even Africa. Of the various homeland candidates, two have enjoyed special attention by scholars.

The first is the Anatolian hypothesis, according to which the ancestors of the Indo-Europeans migrated from Anatolia to southeastern Europe and gradually extended their areas of settlement. It is assumed that the Indo-Europeans spread not only their languages but also the technology of farming. There are basic problems of chronology that arise in this context. The horse, as a prominent animal in mythology and economic life, belongs to the oldest cultural strata of Indo-European culture, dating back at least to the sixth millennium BCE. However, the horse and the wheeled wagon appear in Anatolia and southeastern Europe as late as circa 2000 BCE. According to linguistic and anthropological evidence, the Indo-Europeans established contacts with their Uralian neighbors west of the Ural Mountains as early as the sixth millennium BCE. If the Indo-Europeans had come from Anatolia, their migration to eastern Europe would have taken them too long to have arrived there in time.

The second theory is the Kurgan hypothesis, according to which migration started from eastern Europe (from an area north of the Black Sea and the Caspian Sea) and was directed to the west (into central and western Europe) and to the east (into central Asia and beyond, to the Iranian plateau and into the Indian subcontinent). Kurgan, a term of Tartar origin and transmitted by Russian into Western languages, denotes an earthen grave mound that was typical of the

culture of the early Indo-European migrants. The burial tradition associated with the kurgan grave mounds spread widely into southern Europe and into the Caucasus.

In the nineteenth century, Indo-European studies were mostly carried out by historical linguists. In the course of the twentieth century, other scientific disciplines such as archaeology, anthropology, and culture studies have contributed important data. The breakthrough of genetics in the 1990s—when it became possible to identify the genomic profile of human populations—brought valuable insights also for the study of the early dispersal of Indo-European tribes.

In the area of the putative homeland of the Kurgan people, the findings from various disciplines can be reconciled. The archaeological record shows continuity of settlement since the end of the last Ice Age (ca. 10,000 BCE), and climatological research has produced evidence for a desiccation of the region and the emergence of the steppe landscape. The reconstruction of the socioeconomic vocabulary of Proto-Indo-European reveals that the early Indo-Europeans were pastoralists, a form of subsistence they adopted and practiced in the steppes of southern Russia. A particular combination of genes and their frequencies, the Indo-European genomic profile, which differs from the gene pool of the Uralian peoples farther north and from that of the population in the Caucasus farther south, can be recognized in the genetic map.

From here, the genetic features were transmitted into other regions of Europe through intermarriage of the migrants with local populations whose offspring carry the genes of their ancestors. The frequency of features of the original Indo-European gene pool decreased with a growing distance from the homeland, and this is discernable as gradients in the genetic map. Resulting from the migration movement, the Indo-European proto-language gradually dissolved in the course of the fifth and fourth millennia BCE and split into regional branches. The earliest traces of an intrusion of migrants from the steppe in the west come from a prehistoric cemetery near Varna in modern Bulgaria. Among the grave goods was a scepter with a horse head and the oldest gold treasure of the world, dating

back to circa 4500–4400 BCE. The latest of the big migrations brought the Indo-Aryans to northwestern India in the seventeenth century BCE.

The oldest of these branches is Indo-Iranian, which later split further into the Indo-Aryan and the Iranian branches. These languages (some 300) make up the great majority of the modern Indo-European languages. Other major branches of Indo-European are Slavic (Russian, Bulgarian, Polish, etc.), Germanic (English, German, Swedish, etc.), Celtic (continental Celtic is extinct; Insular Celtic with living languages such as Irish, Welsh, and Breton), Greek, and Armenian. Among the extinct languages of Indo-European stock are those of the Anatolian branch (all languages such as Hittite, Luwian, Lydian, etc., are extinct) and of the Italic branch (except for Latin, which is still used, all other languages of this branch are extinct such as Umbrian, Oscan, etc.) as well as Thracian, Illyrian, Phrygian, Venetic, Tocharian, and several others.

Some of the prominent vehicles of high culture that originated and flourished in antiquity belong to the Indo-European phylum: for example, Sanskrit, Greek, Latin. Most of the languages of the world with more than 100 million speakers each are of Indo-European affiliation: that is, English, Hindi, Spanish, Russian, Bengali, Portuguese, French, German.

In the early centuries of our era, Indic languages such as Sanskrit and Pali spread, as the sacred languages of Buddhism, throughout Southeast Asia. During the colonial age, starting in the sixteenth century, Indo-European languages (English, French, and Spanish in particular) were exported into most regions of the world. Since the seventeenth century Russian spread, as the mother tongue of Russian settlers and as the language of the tsarist empire, into its inner colony of Siberia. Today, Indo-European languages are spoken, as first, second, or additional languages, by several hundred million people whose ancestors were non-Indo-Europeans.

The Settlement of the Gangetic Plain and the Indo-Aryan Invasion Theory

Until very recently, most accounts of the ancient history of the Indian subcontinent told a similar story, that during the second millennium BCE, Indo-Aryan invaders entered India, settling in the Gangetic Plain and possibly dealing a final blow to the waning Indus Valley civilization (the ancient Harappans). Some scholars still subscribe to this theory (or variations), but since the 1970s there has been a growing understanding that the changes in second-millennium India came not from outside but within. Environmental changes and the introduction of new crops drew Indian civilization out of the Indus Valley and into the Gangetic Plain. Concomitant with these environmental and subsistence changes were numerous social changes. From 1900 BCE to 1300 BCE, the Harappan civilization disappears in the Indus Valley, and Vedic civilization appears along the Ganges.

The theory of an Indo-Aryan invasion of India is worth outlining. The roots of the theory must be seen in the observation (made in the eighteenth century CE) that Sanskrit, the language of the Vedas, was related to European languages. Sanskrit, like English, is part of the Indo-European family of languages. For eighteenth-century scholars, it was difficult to reconcile this fact with the racist theories of a superior Europe and an inferior Asia. Dravidian, the other major language in India, is substantially different from the reconstructed Indo-European root language than is Sanskrit, so it was not long before European scholars posited that there were two

ancient racial groups in India, one related to Europeans and one that was indigenous. With the discovery of the Harappan culture and the realization that this culture long predated the Vedas, the scholarly consensus among European historians came to be that the Harappans spoke a form of Dravidian and that Sanskrit was introduced by a later group. The British archaeologist Mortimer Wheeler identified what he thought to be the results of an ancient battle at Mohenjodaro (one of the main centers of Harappan civilization) and argued that a warlike group of Indo-Aryan invaders had come from across the Caucasus Mountains, destroying the Indus Valley civilization and settling in the Gangetic Plain. Although Wheeler's evidence for an invasion proved to be incorrect, this theory was embraced by historians of ancient India and is still perpetuated in introductory textbooks today.

Archaeological work since World War II has shown that the collapse of Harappan civilization and the rise of Vedic society in the Ganges was a gradual transformation and not a sudden development caused by an external invading force. Those scholars who still see change as having come from the migration of people from outside of the subcontinent to India argue for a series of much more complex migrations rather than one large movement. Most scholars, however, see the development of Vedic culture as coming from within India, reflecting internal change as opposed to external pressure. Scholars have recognized that there was no central authority that led the Harappans, no king, and no political capitals. Thus, the transformation from Harappan to Vedic culture may not have felt like a drastic change, and the changes that did occur over 600 years may not have been noticed. Imagine how different your home town was 600 years ago. If you live in North America it probably did not exist! This is not to say that the Vedic society that emerged around 1000 BCE was not very different from the Harappan society that emerged closer to 4000 BCE. In fact, these societies were extremely different from one another. Rather, this realization reflects developing understandings of what caused change in ancient societies and how complex these causes actually were.

One of the most important events associated with this cultural transformation was the

➤ SCHOLARLY CONTROVERSIES—RACISM, NATIONALISM, AND INDIAN LANGUAGES

Part of the difficulty in understanding the changes in Indian society in the second millennium come from how historical accounts of these events have been used in modern political discourse. For the British, tales of a group of militaristic Indo-Aryans invading and civilizing India provided historical precedent for their own imperial interests in the subcontinent. Adolf Hitler also used India's Indo-Aryan heritage for his own political purposes. Following some of the spurious nineteenth- and early-twentieth-century scholarship equating race and language, he saw these Indo-European language users as an ancient warlike racial group, using the term "Aryan" to describe them and a host of other pseudohistorical groups. It is now difficult to conceive of Aryans and Aryan languages without the baggage of Nazi pseudo-scholarship. In fact, the term *arya*, when used in the Vedas, does not refer to a racial group at all. It is better translated as "noble" and does not line up neatly with any particular ethnic group. It is quite hard to identify a clear and consistent difference between Aryan and non-Aryan in these texts. The supposed Indo-Aryan conquest of India also plays a role in modern Hindu nationalism. The hierarchy implicit in the discussion of Sanskrit speakers conquering Dravidian speakers is still controversial and fuels various conflicts, with the northerners generally associated with the Aryans and the southerners associated with the Dravidians. The argument that there was no Aryan invasion may be equally politically loaded within the context of modern Indian nationalism. Scholars who argue vehemently that all of the changes associated with the Aryans came from internal developments within India may be arguing this less on the basis of the evidence and more out of their own nationalist sentiments.

—Kevin M. McGeough

disappearance of the Ghaggar-Hakra River (probably identified with the Saraswati River mentioned in Vedic texts). Many of the important Harappan cities were situated along this river. As its course gradually shifted, through a combination of drying up and intermingling with the

Indus River systems, these cities were no longer supplied with fresh water for drinking, let alone for agriculture. So, very gradually, these settlements were abandoned in favor of locations closer to dependable water sources.

Movement into the Gangetic Plain became possible with the introduction of new crops, especially rice but also sorghum and pearl millet. The Gangetic Plain is monsoon plain, which is unsuitable for wheat and barley agriculture, the staple crops of the Harappan subsistence regime. These summer crops depend on very different agricultural practices than wheat and barley, and thus the people who moved to the Gangetic Plain were forced to develop new social and economic practices in order to prosper.

Trade with Baluchistan and western Asia, one of the hallmarks of Harappan civilization, also declined. This is evident from the marked decrease in imports from western Asia found in sites in India dating to the second millennium and the lack of Indian artifacts found in western Asia in this same period. It is difficult to isolate the causes of this decline in trade contacts and whether this was a cause or a symptom of Harappan decline. After 1300 BCE, there is clear evidence of the introduction of the domesticated camel and horse into India, thus facilitating trade with central and eastern Asia.

The linguistic evidence for an Indo-Aryan invasion or migration is quite a bit more complex, and there does not seem to be consensus among linguists about what the evidence proves or among historians about how much faith to have in linguistic arguments. Generally, the linguists working on this issue have tried to identify how Sanskrit relates to Iranian languages of the same family and how both of these languages relate to the root language (called Proto-Indo-European by linguists). Old Iranian and Sanskrit are clearly very closely related, so when and where did they diverge: in Iran, in India, or outside both regions? Since Iran and the Indus Valley were in constant contact since at least the beginning of the fourth millennium, these questions are not easy to answer.

By about 1300 BCE, the culture of the Gangetic Plains must have seemed quite different from the third-millennium culture of the Indus

Valley. The Indus script was no longer in use; Sanskrit was the dominant language, the language in which the Vedas were written. The Vedas record numerous new social, political, and religious practices, practices with little apparent connection to the Indus Valley civilization. The material culture was also different. Pottery styles in Vedic times differ from those in Harappan times; new motifs are apparent, as are more elaborate styles. The Painted Gray Ware, which was once taken as the material culture of the Aryan invaders, remains a marker of this new culture to archaeologists working in the region. Figurines of horse and camel riders point to the introduction of these domesticated animals, which come to play an important role in India in Era 3. Whether or not one sees these changes as indigenous developments, the results of gradual migrations from the north, or a combination of these factors, the second millennium BCE was a time of remarkable change for the Indian subcontinent.

The Spread of Indo-European Languages

The term “Indo-European” refers to the postulated largely defined and related ethnic groups utilizing the majority of the languages of Europe, central Asia, Iran, Afghanistan, and the northern stretches of India, both past and present. The relationship between these languages and particular cultural attributes among these groups leads many linguistic anthropologists to assign different theories as to the inclusion and the exclusion of certain groups. While it has been suggested that Indo-Europeans existed at one time or another as a large uniform group that split off into various subgroups that retained cultural elements from the original group, historical linguists are

divided as to when this split occurred. The original Indo-European cultural group is believed to have existed anywhere between east of the Black Sea to central Europe and down to the Balkans, although scholars are still in disagreement over the exact location. The eventual breakup of the Indo-European group from this initial geographic region, which occurred over nearly two millennia, resulted in the diffusion of ten major groupings with further subgroupings emerging over time and geographic distance.

The three major branches of Indo-European language that scholars agree originated in the second millennium BCE are Anatolian, Indo-Iranian, and Greek. Anatolian consisted of distinct Hittite languages confirmed by archaeological findings in central Turkey at Hattusas, the capital of the Hittite empire. Documents written in cuneiform script have allowed scholars to distinguish between Old Hittite (ca. 1700–1500 BCE), Middle Hittite (1500–1350 BCE), and Neo-Hittite (1350–1200 BCE). Indo-Iranian encompasses two language groups, Indic (Indo-Aryan) and Iranian. Indic texts in Vedic Sanskrit are believed to have existed in the Punjab during the latter half of the second millennium BCE. However, recent archaeological findings have created considerable controversy as to exactly how related Indic is to Indo-European. Iranian, spoken initially over most of southeastern Eurasia, evolved into Old Persian and Parthian within the geographical confines of modern Iran. Modern Persian, Farsi, evolved from ancient Iranian. Greek (Hellenic) emerged in its first form as Mycenaean Greek on the peninsula and in Crete. It later evolved through the Classical, Hellenistic, Byzantine, and modern forms.

A further two branches, Italic and Celtic, are attributed to the first millennium BCE from which emerged a series of further language groupings. Old Latin is firstly attested in inscriptions (sixth through third centuries BCE) from which evolved Classical Latin. Other Italic dialects, also prevalent in the Italian peninsula, eventually became subsumed within Latin with the rise of the Roman Republic. Celtic languages were spoken in parts of western to southern Europe from central Europe to the Iberian Peninsula and eventually in remote areas of Britain.

Irish, Gaelic, and Gallic are among its most prominent subbranches.

Five branches of Indo-European emerged in the Common Era: Germanic, Armenian, Tocharian, Balto-Slavic, and Albanian. The first Germanic language known to be written is Gothic, from a Bible translation in the fourth century CE. Other groupings would be Vandalic, Burgundian, and Old Norse. These languages were spread throughout central and eastern Europe and in contact with Latin through the Romans. Evidence for Armenian is known from a Bible translation from the fourth century around the Caucasus and the Black Sea region. Tocharian, found in the Tarim Basin in Chinese Turkestan, was found to be from the sixth to eighth centuries CE. From Baltic-Slavic (Slavonic) in eastern and central Europe, evidenced from Bible translations in the ninth century, you get a host of subgroups that diffused down to the Balkan regions coming in contact with Greek and the Greek alphabet. Last, Albanian is known to have existed since the fifteenth century, when it was first attestable in writing from the period.

Where Did the Zhou Come from?

In 1045 BCE, the Western Zhou king (King Wu) overthrew the Shang dynasty and became the leader of most of Shang China. In a few short years, the Zhou had expanded its empire through the East, establishing a pattern for Chinese kingship that would last for thousands of years. Once the Zhou established themselves as the preeminent power in China, there is a substantial amount of information preserved about them. However, for the time prior to their conquest of the Shang, there is less information.

Chinese historians are forced to work with ambiguous ancient poetic accounts of the Zhou and attempt to match these accounts with archaeological evidence. Further complicating the problem is the fact that the Western Zhou dynasty is viewed in a very positive light in the Chinese tradition. This means that people in different regions of modern China are quick to claim descent from the virtuous Zhou. The historian who takes a stand on this issue does so at the risk of undermining local historical traditions.

The traditional account of the origins of the Western Zhou can be found in the *Shi jing*, a collection of 305 ancient poems. In one poem, the Zhou are said to be born of a woman named Jiang Yuan who conceived when she stepped in the footprint of the divine Di. Jiang Yuan gave birth to Hou Ji, whom she abandoned (believing that this was the wish of Di). Hou Ji learned to survive on his own and became the eponymous ancestor of the Zhou people. Another poem in the collection lists the genealogy of the Zhou leaders. One of the leaders, Gu Gong Danfu, brought his people to the base of Mount Qi where, we are told in another poem, he built the city of Qishan. Gu Gong Danfu is described as the grandfather of King Wen, who was the father of King Wu, the king who defeated the Shang.

Tradition holds that the people had been living in a place called Bin (although this reading of the ancient Chinese characters is not entirely certain) and that they had to cross over the Liang Mountains to get to Mount Qi. Identifying the precise locations of where they came from and the location of Qishan is difficult since the ancient place names are not accurately preserved. Bin is typically associated with Binxian, which is in Shaanxi Province, located to the west of the Shang heartland. A small range of mountains, called the Liang Mountains, lies between Binxian and Qishan. This seeming correlation has led historians to generally situate Zhou origins in Shaanxi.

In the 1930s, the historian Qian Mu argued that in fact the Zhou originated to the east of the Shang heartland in Shanxi Province (not to be confused with Shaanxi in the west). Qian Mu was able to show that the place names and geographic descriptions mentioned in the *Shi jing*

may also correlate with locations in Shanxi. Furthermore, Shang oracle bone inscriptions (published in the 1950s) mention a site called Zhou, located in Shanxi.

Archaeological evidence also seems to support Zhou origins in either Shaanxi or Shanxi. A Proto-Zhou material culture assemblage seems to be identifiable in the archaeological record and has been identified at numerous sites. Most important is the analysis of the spatial distribution of various pottery and bronze forms; some scholars believe that a pattern of Zhou movement can be discerned in this material. This is done by correlating material culture excavated from Qishan and material culture that dates to after the Zhou conquest with older forms. Unfortunately, analysis of the evidence can be skewed to support either location as the Zhou homeland.

Recent work suggests that the quest to find the Zhou homeland and trace their migration route to Qishan may be based on premises that are too simplistic. The quasi-historical accounts in the *Shi jing* should probably not be seen as an ancient attempt to preserve specific information about the Zhou past. Rather, these accounts should be understood as an ancient attempt to understand the relationship of the Zhou to the rest of China and to simplify that relationship in a way that was meaningful (and possibly politically advantageous) to ancient contemporary readers and listeners. Likewise, more recent archaeological theory has shown that migrations and movements of people do not necessarily correlate with the movements of material culture. These older “pots equal people” theories have fallen out of fashion, so attempting to trace a Zhou path in pottery or bronze may be misleading. Finally, the Zhou and the Shang categories may not be as fixed as they seem in the traditional accounts. The lines between Shang culture, Zhou culture, and other Chinese cultures from the period were likely much more blurry than the historical traditions suggest. Given recent reevaluations of the relationship between the Xia and the Shang, a similar reevaluation may be appropriate for the Shang and the Zhou. Material cultural changes associated with the advent of Zhou leadership may better reflect shift-

➤ THE LI—PROTO-ZHOU MATERIAL CULTURE

Bronze li from the Zhou dynasty, 1100–771 BCE. (Asian Art & Archaeology, Inc./Corbis)

One of the primary pieces of evidence that archaeologists have used to try to identify Zhou origins is the *li*. This is a form of ceramic cooking pot, very distinctive because of its three legs (called lobes by ceramicists)—its own built-in tripod. This type of pot is common throughout China immediately prior to and after the Zhou conquest of the Shang. However, the style (especially the shape of the lobes) varies from region to region.

■ Introduction: Movement and Material Culture

The movement of ancient material culture is the most reliable way in which archaeologists are able to trace ancient travel. By plotting the appearance of the same types of material culture over different locations through time, archaeologists are able to reconstruct the ancient paths that people took long after those people have vanished. For an archaeologist to be confident that he or she has identified an ancient migration by the distribution of artifacts, he or she must have found the material in at least three locations: (1) in the place where the people originally lived, (2) along the route that the people traveled, and (3) in the final location of the people. Without finding the same material culture in all three of these types of locations, there is really no evidence that the movement took place. The temporal distribution must also line up. In other words, the material culture found at the original location must be earlier (or at very least contemporary) with the material found at the end location. It is this temporal distribution that allows an archaeologist to identify which was the starting point and which was the end point.

Identifying migration is not as simple as this, however. An archaeologist must be certain that the movement of a particular material culture assemblage should be associated with migration and not other kinds of activities, such as trading or plundering. Early archaeologists often equated “pots with people,” which is an oversimplistic equation at best. To take an example from modern times, imagine an archaeologist plotting the distribution of Coca-Cola bottles. Coca-Cola bottles can now be found all over the world. This is certainly a meaningful observation, and it has some important implications for understanding the present day. Yet the archaeologist would be incorrect in positing that there had been a mass

migration of “Coca-Cola people” that began in North America and spread throughout the world. The same problem should be considered in regard to other finds from early periods; the movement of material culture was culturally significant but not necessarily indicative of an ancient migration.

Below, three examples of migrations reconstructed from material culture are presented: the arrival of new groups on the island of Malta, the so-called Uruk expansion from ancient Sumer, and the first settlements in the Caribbean. These are all situations where archaeologists have been able to plot the movement of material culture over time.

—Kevin M. McGeough

The Arrival of the Tarxien Cemetery and Borg In-Nadur Cultures in Malta

There is no clear reason why the Temple culture of Malta seems to have disappeared. Various theories have been put forward, yet no single theory has been completely accepted. It is probable that there was not a single cause for why the highly organized Temple people abandoned Malta.

One of the issues surrounding the disappearance of Temple culture is whether or not the islands were actually abandoned and left uninhabited for a number of years. Could it be that only a few people remained on the islands and thus a certain kind of continuation existed between the people who erected the magnificent temples and those who came afterward? This does not seem likely since there is not much cultural continuity between Temple culture and the cultures that arrived in the Bronze Age.

Scholars are fairly certain that by 2500 BCE, the Temple culture on Malta had vanished. Some time afterward a new group of people arrived on Malta, bringing new types of buildings, a different design program, new pottery, and a different approach to the artistic representation of the human form. This new culture also introduced the use of metal, mostly copper, in the early stages of this period (even though the culture is referred to as “Bronze Age”). These people may have come to Malta from the eastern Mediterranean. The Cycladic Islands are a likely place of origin, due to similarities in material culture: cyclopean structures (buildings made of large, undressed stones), pottery shapes, and representations of the human form that are reminiscent of Cycladic statues.

Cremation was introduced by the so-called Tarxien cemetery people. This name has been applied to the first phase of the Bronze Age, the third period in the Maltese prehistoric sequence. Over the ruins of the Tarxien temple complex, which seem to have been abandoned around 2500 BCE, the newcomers to the islands established their cremation cemetery. These made use of the upright stones that were still standing to act as a shelter for their raging fires. The bodies were placed on wooden pyres, and the remains were then placed in funerary urns. Although this kind of burial has been noted during the Tarxien Cemetery phase, only scant remains have actually been preserved.

One of the most significant changes to the Maltese prehistoric sequence associated with this period are the so-called fortified villages in which the citadels had a distinct location. Not much material has actually been recovered from these sites, but a good number of sites have been identified on flat-topped hills. These hills usually offer natural protection, at least on three sides. If the hills are surrounded by steep slopes, the inhabitants of the islands did not bother to build any artificial defense walls. Yet in certain places, the hills chosen were surrounded by three slopes on three sides of the hill; defensive structures (usually walls constructed of large boulders) had to be built on the fourth side. The style of building is known as cyclopean, in which these large irregular boulders were placed next to each other

and thus formed a formidable wall of defense. The best fortified walls that have survived are that of Borg in-Nadur, the type site of the second phase of the Bronze Age.

Built a few meters away from the ruins of a temple belonging to the previous Temple period, the Borg in-Nadur village has only survived partially. The most impressive are the walls that surround part of the landward side, as on three sides of the site there are the slopes of the hill. The ancient walls have also a D-shaped form, and the entrance to the enclosure seems to have been hidden and protected by an outwork. Sophisticated defense works similar to the Borg in-Nadur remains have not yet been identified in earlier phases on Malta, suggesting that this construction style reflects the arrival of a new group of people.

The remains of huts were discovered behind the walls, indicating the presence of a small village. Yet the area is small and possibly would not have been large enough for the whole village community to live there. Perhaps the enclosed area was a citadel, where villagers could retire to in case of an attack. This is further indicated by the contemporary remains found along the shoreline, indicating that activity took place outside of the walls as well. A number of bell-shaped cavities have been discovered, (although many of these have been submerged by the rise in sea levels). These rock-cut cavities could have been used for water and/or grain storage. Since they are situated just on the shore, it has been suggested that these cavities could have been part of a still unknown import-export trade practiced by the prehistoric communities living on the islands.

The Bronze Age period had another influx of newcomers, and it seems that they set up their settlement on another flat-top hill, close to the high cliffs of the coast. This phase, known as the Bahrija phase after the site where it was first identified, ended along with the Borg in-Nadur phase when contact with the Phoenicians intensified, starting with more frequent trade with the islands and leading eventually to the establishment of Phoenician trading outposts among the local inhabitants. By 700 BCE, the Phoenicians were well established on the islands.

The Uruk Expansion

Between 3500 and 3100 BCE (the Late Uruk period) the influence of southern Mesopotamia expanded far beyond the confines of the Tigris and Euphrates. The Uruk period in Mesopotamia was a time of urbanization and the period in which writing and monumental art emerged. Uruk (biblical Erech) was the largest site in southern Mesopotamia (over 247 acres [100 hectares] in size) at this time, and this may have

been the center of many of these changes. These societal transformations spread far beyond the city of Uruk during this period, along with Uruk material culture; the exact nature and processes behind this expansion are unclear, but no doubt this was an important period for the spread of literate urban life throughout Asia Minor. Generally, scholars refer to this movement of Uruk culture out of southern Mesopotamia as the “Uruk expansion.”

Mesopotamian material culture from the Uruk period has been identified at sites in northern Syria and Anatolia and as far west as the Mediterranean. In this area, the influence of southern Mesopotamian material culture on local material culture seems to have been relatively minor in that Uruk materials such as pottery and writing existed alongside local forms of material culture. There is also some evidence that Uruk culture may have influenced Egypt, since Egyptian material culture at this time incorporated elements from Mesopotamia. The Egyptians incorporated cylinder seals, artistic motifs, and various types of architecture and architectural decorations that originated in Mesopotamia, although the nature of the two regions’ contact with another at this stage is not entirely understood.

Uruk period links to southwestern Iran during this period were even more intense, and it is possible that Uruk colonies were established in northern Mesopotamia and Iran. If these were not colonies, then perhaps local people were attempting to emulate Uruk materials and lifestyles. However, given the dramatic similarities in material culture between Uruk and southwestern Iran at this time, it is most likely that these were colonies of some sort. It is not clear how much (if any) political control Uruk held over the Iranian plateau. Likewise, it is unclear what the purpose of this expansion of Uruk culture was. Some scholars have argued that the people of southern Mesopotamia were attempting to acquire resources such as timber, stone, and metals (since these are absent in the resource-poor Mesopotamian floodplain).

—Kevin M. McGeough

▶ BEVELED RIM BOWLS

One of the most distinctive types of Uruk material culture that is found at sites from the Mediterranean coast to the Iranian Plateau is the beveled-rim bowl. Named for its distinctive beveled edges, these bowls were mass-produced ceramics made from very coarse clay (tempered with straw). Often, the finger marks of potters are visible on the insides of these cheaply made ceramics. What these bowls were made for is still a mystery, although numerous suggestions have been offered. Some have argued that these were ration bowls for the state workforce, since they seem to have relatively fixed sizes. Others have argued that perhaps they were used for bread or for yogurt, both commodities that were typically stored in mass-produced vessels in the Near East. Salt may also have been stored and transported in these vessels. Finally, religious uses have been suggested; these may have been “official” feast bowls or votive bowls for temple offerings.

The Settlement of the Caribbean

The first settlements in the islands of the Caribbean occurred between 1000 BCE and 300 CE. From 4000 BCE onward, waves of settlers have continuously moved to these tropical islands. The first settlers to these islands had to adapt to a new environment with mild and pleasant weather but with very different fauna from their homelands. Those cultures that thrived in the new island environment learned to subsist on marine resources and limited horticulture, sub-

sistence regimes that typically were vastly different from those they left behind.

Around 4000 BCE, the first Caribbean settlers left the Yucatán Peninsula and journeyed to the islands of Cuba and Hispaniola (present-day Haiti and the Dominican Republic). Their flaked stone tools (which make up most of what has been recovered archaeologically) are very similar to those found in the Yucatán, so scholars are quite certain that this is where these people originated. This material culture is called Casimiroid, after the site of Casimiri in the Dominican Republic. There is one site in Puerto Rico—the Cerillo site—that may be considered Casimiroid, but this is uncertain. By about 2000 BCE, the people of Cuba and Hispaniola had developed an independent material culture tradition that is especially noteworthy for ground stonework.

The next wave of Caribbean settlers that has been identified by scholars arrived in the Lesser Antilles and Puerto Rico around 2000 BCE.

► THE CIBONEY

Around 2500 BCE, a group of people known as the Ciboney left Venezuela for the Caribbean. While the early history of this group is obscure, people claiming descent from this group still live in parts of Florida and Cuba today. Identifying early Ciboney material culture is difficult; scholars identify some shell middens, tools, and canoes as Ciboney. However, the material culture varies substantially from island to island. The name, which means “cave dwellers,” is derived from the language of the later Arawak Indians (or Taino) who seem to have conquered the Ciboney (or at least forced them to the margins of island life). The terminology that scholars use to discuss the people of the Caribbean can be quite confusing, since there are a few different conventions for use. Generally, when scholars refer to the Ciboney, they are referring to early settlers who did not use pottery and did not farm.

—Kevin M. McGeough

These settlers had come from the coast of South America, bringing with them distinct tools made in chert. Living in small villages, the people of ancient Puerto Rico and the Antilles lived on marine life hunted on reefs and small game hunted in the forest.

Lapita Complex

The pottery now called Lapita was discovered first in 1907 on the small island of Watom, Papua New Guinea. But it takes its name from a site in New Caledonia where quantities were excavated in 1952. Sites containing it have now been found from New Britain in the west to Samoa in the east.

The distinctive aspects of Lapita pottery are its decoration and shape. The most elaborate decoration is geometric in style, often including stylized faces. This decoration is made with toothed stamps, which may contain up to 15 teeth per 0.4 inches (1 centimeter). Some large-bellied pots are nearly 3 feet (1 meter) tall with elaborate shoulders and rims and covered with a red slip. The pottery is, however, handmade, often with poor-quality material and badly fired.

The people who made this pottery were the first settlers of Remote Oceania. This extensive region was occupied in a very short time. The earliest sites, in the Bismarck Archipelago, are dated to about 1200 BCE. By 1000 BCE Lapita pottery was being made in New Caledonia, 1,367 miles (2,200 kilometers) to the southeast, and by 800 BCE in Samoa and Tonga 2,485 miles (4,000 kilometers) to the east. This is the earliest large-scale maritime colonization in the world, and the voyagers clearly had good sailing canoes and navigational skills.

The term “Lapita complex” has been developed because sites with lots of Lapita pottery show many other common features. Numerous shell artifacts were made of *Conus*, including fishhooks, bracelets, armbands, rings, beads, and pendants. Many of the sites are stilt villages on small offshore islands or protected peninsulas with good access to the sea. People were agriculturalists and kept domestic pigs, dogs, and chickens. The recent discovery of a cemetery in Vanuatu revealed bodies buried with or in pots and grave goods including shell jewelry and human skulls. Nearly all Lapita sites contain some obsidian, drawn from sources in the Bismarck Archipelago. Stone axe/adzes of new asymmetrical cross-section also occur.

While the fact of colonization is undoubted, the source of it is still strongly debated. The most widely accepted suggestion is that the colonizers were migrants, initially from Taiwan. The claim was originally based on the idea that Polynesians were so different from Melanesians that they could not possibly be descended from them. Today the strongest evidence is linguistic. All Remote Oceanians speak languages of the Austronesian family, as do some coastal New Guineans and all southeastern island Asians. Linguistic prehistory traces the origins of this family to Taiwan

DISTRIBUTION OF LAPITA POTTERY

about 6,000 years ago. The archaeological evidence for such a migration is, however, very slight. No Lapita pottery has been found in Taiwan or the intervening areas, although red-slipped ware is common throughout the region from about 2000 BCE.

Recent biological evidence deriving from various aspects of the human genetic makeup is inconclusive. Some studies suggest links between Remote Oceanians and southeastern Asians, while others show no such link. Similarly, claims that Austronesian speakers in Near Oceania are biologically distinct from speakers of other older non-Austronesian languages are disputed by other analysts.

On the other hand, Lapita pottery seems to appear quite suddenly at the oldest sites, in the Bismarck Archipelago, and its very early examples are among the most elaborately decorated. This suggests that the technology of pot making

was likely derived from elsewhere. Allied to this are the possibility that Bismarck Archipelago obsidian was traded to the eastern Philippine islands by 3,000 years ago and the fact that Lapita decoration is very similar to that found in other media in this area of the Pacific and would have been easily transferred to pottery. Thus, the Lapita complex may well represent a fusion of ideas and technologies in the Bismarcks, perhaps with a few people arriving from the west.

But what stimulated the great migration of people out into Remote Oceania, people whose descendants occupied all the islands of the Pacific, is not clear at all.

—Peter White

➤ LAPITA NAVIGATION

Lapita navigation was based entirely on observations of the world around the sailors and on their traditional knowledge. They had no compasses or other mechanical aids.

Initial exploration, of course, was not navigated. As the archaeologist-sailor Geoff Irwin has shown, people almost certainly set out exploring upwind so that when they reached the limit of their food or patience they could return safely and quickly.

But once settlements were established, there continued to be movement and exchange between them. Judging from Pacific islanders of the recent past—our only real source—the most important techniques were:

- Observing the succession of stars over particular points in the east and west horizon and their relation to other star patterns.
- Dead reckoning, allowing for currents, swell patterns, winds encountered, and the angle of the wake. Modern experiments show that

errors within these observations tend to cancel each other out in the hands of an experienced navigator.

- The observation of bird behaviors, especially of those species that returned to land to roost every night.
- Cloud patterns, as clouds often form over islands in the tropics.

The other important point to remember is that most targets were large. Many islands lie within archipelagoes, which presented targets up to 20 degrees wide. So navigators could afford to be a bit off. Single islands such as Easter Island seem to have been rarely or never visited.

■ Introduction: The Kingdom of Punt

The Kingdom of Punt was a minor trading partner with the ancient Egyptians all through the dynastic period, at least Dynasties five through Dynasty twenty. The Egyptians described Punt as a paradise where every good thing, from gold to exotic animals (rhinos, giraffes, baboons, etc.), existed in abundance. However, the Egyptians were mainly interested in obtaining myrrh for use in temple ritual, as it could not be found locally. Almost nothing is known about the Kingdom of Punt from its location to its culture. The ancient Egyptians are the only ones who ever refer to Punt, and their mentions of Punt were usually fleeting. However, Queen Hatshepsut (Eighteenth Dynasty) created

a series of reliefs with texts that show and describe an expedition to the land of Punt. These reliefs are the only depictions of the land of Punt from ancient Egyptian art and form the basis for most of the knowledge about Punt.

The location of the Kingdom of Punt is largely a mystery. The ancient Egyptians did not create maps, nor did they give detailed directions on how to get there. A number of theories have arisen as to its possible location based primarily upon its trade goods; these places include Yemen, Bahrain, India, Ethiopia, Sudan, Eritrea, Somalia, Mozambique, the Sinai, and Phoenicia. The most likely candidate is that of eastern Sudan/Eritrea, located between the fifth cataract

of the Nile and the mouth of the White Nile on the west and stretching east to the Red Sea. All the trade goods described in texts and depicted in art as coming from Punt can be found in this area. It must be noted that the placement of Punt in modern Yemen cannot be ruled out. But this would mean that the Yemen Puntites were part of a much larger and more complicated trade network that included India and southern Africa. The location of Punt in East Sudan and Eritrea is a simpler explanation. Until more archaeological study can be done in these areas, the debate will continue.

—*Vanessa Smith*

Egyptian Expeditions to Punt

Punt was of great interest to the Egyptians, who not only wanted the myrrh resin but also myrrh trees so that they could cultivate their own resin. In fact, all of the historical evidence for the Kingdom of Punt comes from Egyptian accounts of expeditions to this land. All of these expeditions were organized for trade, and it was clear that Egypt's interest in the land was mostly economic.

The first reference to Punt is from the Palermo Stone, which recorded the reigns and deeds of the kings of the first five Egyptian dynasties. The Fifth Dynasty king Sahure had myrrh and electrum (a gold and silver alloy) brought from Punt. During the Sixth Dynasty, a man named Harkhuf traveled to the land of Yam, whose exact location is also unknown but seems to have been near Punt. Harkhuf wrote a diary of his travels on his tomb walls in Aswan and included a letter from the boy king Pepi II, who is very excited to learn that Harkhuf is returning from an expedition with a pygmy to dance in the temple. The letter states that the pygmy is to be guarded very carefully so that he does not fall off the boat on the trip back. The king's letter also mentions that Harkhuf is returning with goods from the land of Punt but clearly shows the king's preference for the pygmy. Slightly later in the reign of King Pepi II, the autobiography of Pepinakht describes an expedition to the Red Sea coast to retrieve the body of Anankht, who was killed by desert tribes while assembling a boat to travel to Punt. Although this reference to

Punt does not describe its location or its goods, it is important in that it describes one of the routes that the Egyptians used to travel to there. The king's letter to Harkhuf indicates that he traveled on the Nile, whereas the inscription of Pepinakht indicates that Punt could also be reached via the Red Sea. These references help in determining the most likely location of the land of Punt as eastern Sudan.

Kings also sent expeditions to Punt during the Middle Kingdom. A graffito written by a man named Henu was found in the Wadi Hammamat, which was the overland road between the Nile Valley and the Red Sea. In the graffito, Henu states that he was sent to Punt by King Mentuhotep III Sankhkare (Eleventh Dynasty) via the Red Sea in order to get myrrh.

The ancient Red Sea port of Sawaw (present-day Mersa Gawasis) provides further inscriptional evidence of trips to Punt from several poorly preserved stelae. Three stelae record one or more trips to Punt during the reign of Senwosret I of the Twelfth Dynasty. The stele of Vizier Intefoker records that 3,756 people (including 500 sailors) traveled through the Wadi Hammamat to assemble boats for the expedition to Punt. Another stele dates to the reign of Senwosret II (Twelfth Dynasty) and records the successful return of a mission to Punt.

Perhaps the best-known expedition to Punt comes from the reign of Queen Hatshepsut in the New Kingdom (Eighteenth Dynasty). One whole wall from her mortuary temple called Deir el-Bahri in Thebes is covered with drawings of the journey to Punt, negotiations with the Puntite chiefs, the return journey, and the presentation of the booty to the god Amun. The Hatshepsut inscriptions are the only ones that depict the land of Punt itself. The people are shown to dress somewhat like Egyptians, but they have long, thin beards. Their houses are dome-shaped on stilts and are reached by ladders. The local flora and fauna are also depicted: dom-palm trees, ebony trees, baboons, a giraffe, and a rhinoceros are but a few. Despite the fact that the expedition returned with all sorts of exotic goods that clearly delighted the Egyptian court, myrrh was the main reason for the trip.

Queen Hatshepsut's successor, King Thutmose III (Eighteenth Dynasty), is famous for his

► THE SHIPWRECKED SAILOR

The Middle Kingdom fairy tale called the “Shipwrecked Sailor” recounts the story of a sailor who is washed up on a deserted island paradise somewhere in the Red Sea. The island is uninhabited except for a huge talking snake more than 50 feet long. The sailor befriends the snake, and they recount their separate stories of woe (the sailor’s shipwreck and the death of the snake’s family). The snake is so grateful for having a friend that he tells the sailor his future, which includes returning safely to his family and being lauded by the king. The sailor, in turn, is so overjoyed at learning that he will return safely home that he tells the snake he will make food offerings and send back incense, perfumes, spices, and oils as gifts. The sailor then tells the snake that he believes that the snake is a god. Upon hearing this, the snake laughs and says that no gifts were necessary, for he is the ruler of Punt and therefore controls all the myrrh. Although a fable, the “Shipwrecked Sailor” emphasizes how important myrrh was to the Egyptians. It was a gift for the divine.

—Vanessa Smith

expansion of the Egyptian empire to the north into Syria and expanding territories south in Sudan. He chronicled his exploits at the temple of Karnak and included depictions of the strange flora and fauna that he saw while on his travels. In years 33 and 38 of his reign, Thutmose III annals recount that in the first instance 2,136 gallons and in the second instance 304 gallons of dried myrrh resin were brought from Punt. It is unclear from the annals whether Thutmose III sent an expedition to Punt or the Puntites traveled to Egypt to trade. Three nobles tombs, from the reigns of Thutmose III and Amenhotep II (a total time span of about 80 years), record visits to Egypt by people from Punt. The tomb of Puyemre shows King Thutmose III inspecting 7,634 gallons of myrrh as well as myrrh trees, ivory, ebony, and gold. The tomb of the vizier Rekhmire depicts Puntites offering myrrh, ebony, ivory, gold, ostrich feathers, ostrich eggs, leopard skins, live baboons, and a cheetah. The tomb of an unknown man depicts the boats of the people of Punt as raftlike with black triangular

sails—very different from depictions of Egyptian boats. A graffito from the Sinai dated in the year 36 of King Amenhotep III tells how an official went to the seacoast to receive visitors from Punt. Under the reign of the heretic king Akhenaten, also known as Amenhotep IV (Eighteenth Dynasty), the tomb of Meryre shows the Puntites visiting the new capital city of Amarna and offering myrrh to the king.

During the Nineteenth Dynasty, there are references once again to Egyptian expeditions to Punt. King Seti I, from his temple at Abydos, tells of the many ships sent to Punt to get myrrh. His son, King Ramses II, from his temple at Abydos, recounts planting temple gardens with myrrh trees brought from Punt. Ramses III (Twentieth Dynasty) sent the last known expedition to Punt via the Red Sea route to bring back myrrh.

After Ramses III, there are no more mentions of Punt from ancient Egypt. Trade with Punt may have continued but simply went unrecorded. References to Punt are not found in the literature from any other culture, such as the Greeks or Romans. It may be that the sociopolitical design of Punt changed and that it ceased to be recognized as the culture of Punt.

Hatshepsut’s Reliefs

The Punt reliefs commissioned by Queen Hatshepsut are extremely detailed both in illustrations and text. The reliefs offer the ability to study

not only the little-known culture of Punt but also the political situation in Egypt during the queen's reign, since Queen Hatshepsut emphasizes a close connection to the god Amun-Re throughout the reliefs as a means of legitimizing her reign. The drawings (and their captions) of the land of Punt are the only known representations of that culture and form the basis of all discussions about Punt. The texts underscore the importance of myrrh to ancient Egyptian religious practices (burned as incense in the daily temple rituals at the hundreds of temples all over Egypt) and the fact that the Egyptians would travel a very long way to get it.

The New Kingdom queen Hatshepsut (Eighteenth Dynasty) came to power by taking power from her nephew and stepson King Thutmose III, for whom she had briefly acted as regent. Queens rarely held sole rule in ancient Egypt, and their reigns were generally short and came at times of political instability. Queen Hatshepsut's reign was an exception and is marked by widespread trade with neighboring territories and large building projects including her mortuary temple at Deir el-Bahri. Inscriptional evidence from her monuments as well as from those of her courtiers suggests that during Hatshepsut's reign there was trade with places as far away as Cyprus, the Levant, Minoan Crete, Mycenaean Greece, the Sudan, and Punt.

The mortuary temple of Deir el-Bahri is situated on the west bank of the Nile River near the present-day town of Luxor. The temple is known as a terrace temple and consists of three levels, which are built into the sides of the high desert cliffs. Many of the scenes carved into the temple walls emphasize the queen's divinity in an attempt to legitimize her reign. One of these scenes involves a command given to the queen by the god Amun-Re, an especially prominent deity in the Eighteenth Dynasty, to send an expedition to the land of Punt in order to get myrrh. In a very long inscription complete with illustrations placed on the middle terrace on the south side of the temple, Hatshepsut recounts the oracular statement from Amun-Re, the trip to Punt, the return trip, and the triumph that followed. These reliefs are the only ancient Egyptian depictions or descriptions of the land of Punt. As such, they represent our only knowl-

Redrawn from stone reliefs on the tomb of Hatshepsut at Deir el-Bahri, the illustration depicts an Egyptian trading voyage to the land of Punt. The hieroglyphic text describes the cargo acquired at Punt, consisting of ebony, ivory, gold, and a live panther. (HIP/Art Resource, NY)

edge of the nature of that land, its culture, its geography, and its ecology.

The narrative begins with a scene showing five Egyptian boats leaving the Red Sea coast to begin their journey to Punt. The boat decks are empty of cargo in anticipation of the bounty that they will bring back from Punt. The accompanying text states that they are going to Punt at the command of the god Amun-Re and in order to glorify Queen Hatshepsut.

The next scene in six registers, or lines, portrays the Egyptian expedition's arrival and the Kingdom of Punt itself. In the first register, the chief of Punt, his wife, two sons, a daughter, and their entourage receive the royal envoy and the Egyptian Army. The Egyptians present the Puntites with their trade goods: gold, weapons, and jewelry. This is the only depiction of Puntite women from ancient Egyptian art. The appearance of the chief's wife, named Aty, departs from the stylistic and artistic norms of Egypt. She is shown with a long braided wig and a sheer linen skirt—both fashion norms for Egyptian women—but that is where the similarities end. Aty is very obese with pendulous breasts and fleshy rolls cascading down her tummy and over her knees, ankles, and elbows. Close behind Aty is her daughter, whose name is not given. The daughter, while not obese like her mother, is depicted with pendulous breasts, and her limbs are plumper than stylistic norms, implying that she is on her way to matching her mother's ample

► THE ORACULAR COMMISSION FROM AMUN-RE

The text accompanying the Hatshepsut reliefs recounts the original commission of the expedition to Punt by the god Amun-Re. One day when Hatshepsut was praying before the god's shrine, he spoke to her and told her to make an expedition to Punt in order to get myrrh for him. Amun-Re goes on to tell her that he has always intended that she rule Egypt and that her power spread to all the lands, including Punt. Of course, Hatshepsut is using this text to legitimize her usurpation of the throne from her nephew and stepson, Thutmose III. Amun-Re then makes a long speech about Punt and how no Egyptians had ever reached Punt before, which is false, as expeditions to Punt were undertaken as early as the Fifth Dynasty. Amun-Re tells Hatshepsut that Punt is a paradise that he made as a sort of holiday resort for gods, literally a place to divert his heart. He says that the people of Punt revere him, and because he wishes it, they will revere Hatshepsut as well. Finally, he asks that Hatshepsut plant myrrh trees in a garden in the temple (presumably Karnak temple) so that he can be offered fresh myrrh incense and be bathed in myrrh ointment daily.

—Vanessa Smith

form. The second register depicts the Egyptian envoy in front of his tent receiving the chief of Punt and his portly wife, who present the envoy with a meal and the Puntite trade goods.

All six registers depict the land of Punt dense with trees and with the native houses, flora, fauna, and Puntites at work. The houses of Punt were dome shaped and sat on stilts with a ladder to reach the door. Most likely the houses were made out of organic materials—timber and reed or grass mats—that often are not preserved in the archaeological record, one reason why proving the ultimate location of Punt may be extremely difficult. The people of Punt are shown at work cutting ebony, carrying myrrh trees, collecting myrrh resin, and tending cattle. The local wildlife (a giraffe, a rhinoceros, baboons, and various birds) reside among the trees, ignoring the nearby workmen. Punt is depicted as an idyllic land with plenty of food, trees, animals, and happy people. Interestingly, the Egyptians

do not remark on the apparent primitiveness of Punt society in relation to their own, even though the barbarity of foreign societies is a favorite theme among the ancient Egyptians. The cordial nature of the relations between the Puntites and the Egyptians shows exactly how desperate the Egyptians were to get myrrh incense for their temples.

The next scene in the story of the Punt expedition portrays the Egyptians loading two ships with live myrrh trees, pots of myrrh resin, ivory tusks, and baboons and three ships already under sail back to Egypt. The accompanying text gives a long list of the items that they have loaded onto the ships. It also states that the myrrh is destined for the temple of Amun-Re.

After the departure scene, the Egyptian envoy and some people of Punt present the goods to Queen Hatshepsut, including live myrrh trees, myrrh resin, baboons, and short-horned cattle. The captions tell of the far-reaching power of the queen and how the Puntites pray for peace from her and then tell her how great she is. Subsequently, the queen offers the goods to Amun-Re with a list of exactly what she is presenting, which includes (in addition to the goods above) electrum, eye paint, throw sticks (a type of weapon), ebony, ivory, shells, a live panther, a giraffe, ostrich eggs, many panther pelts, and 3,300 cattle. All the goods are shown lined up or stacked on tables, and there are two heaps of myrrh, one the height of a man and the other twice the height of a man. Part of the queen's presentation to the god Amun-Re includes her weighing and counting all the items. Although exact numbers are not given, the items from Punt are said to be in the millions.

The final scene depicts Queen Hatshepsut announcing to her court that the expedition to Punt was a success. The queen is enthroned in front of three of her courtiers. Around the courtiers is a very long text, which records the queen's speech. There is an introduction that says that Queen Hatshepsut held court in year nine of her reign, which suggests that the expedition to Punt took place within the previous year. The queen opens by saying that because she makes wonderful offerings to the god Amun-Re, he is very happy and loves her very much (another attempt at legitimating her rule). She

goes on to state that Amun-Re commanded her to send an expedition to Punt in order to bring back myrrh and especially to make a garden for him. After this the text becomes too broken to read.

The Resources of Punt

The main product from Punt that the ancient Egyptians were interested in was myrrh. Myrrh is the sap from the myrrh tree (*commiphora myrrha*), which when burned gives off a very fragrant aroma. Myrrh trees did not grow naturally in Egypt but were found in East Africa, southern Arabia, and India. The Egyptians used it in mummification rituals, medicines, and cosmetics, but its primary purpose was incense. During the daily temple ritual, incense was burned in front of the god's statue in order to purify the air. Egypt required a steady supply of myrrh in order to service the hundreds of temples all over the country. The Egyptians frequently brought back not only dried myrrh but also live myrrh trees from Punt in the hope of starting their own supplies. Texts relate that these trees were planted in temple gardens. Any other products that Egypt received from Punt, although welcome, were secondary.

Ebony and ivory were another major component of trade between Egypt and Punt. Ebony trees were found in the same regions as myrrh trees: East Africa, southern Arabia, and India. Ebony was used in furniture making and was a luxury good. Ivory typically comes from the teeth of three animals: whale, hippopotamus, and elephant. Hippopotami lived in the Nile

➤ GETTING TO PUNT

If Punt was indeed located in East Sudan/Eritrea, the Egyptians describe two ways of getting there. The first was to travel all the way down the Nile River directly to Punt. But this journey is not as easy as it sounds, for the Egyptians had to go around at least five cataracts, or areas of the river, that were too rocky to be traveled by boat. Therefore, at every cataract the Egyptians had to haul the boats out of the river and carry them overland until the water became navigable again. Another hazard taking the overland route came from the fact that in many places along the Upper Nile River the desert reaches all the way to the river's edge, meaning that the Egyptians would have to pack all their food for the trip. The more popular and perhaps easier route to Punt was via the Red Sea. Numerous texts recount the construction of boats at Thebes, sailing them up to Koptos, disassembling them, and carrying the parts through the Wadi Hammamat, the east-west road through the desert from the Nile Valley to the Red Sea coast. The boats were reassembled at the Red Sea and sailed down to Punt, which seems to have been located along the coast. The sea route required a massive undertaking. The stele of Vizier Intefoker (Twelfth Dynasty) states that he took 3,756 people through the Wadi Hammamat to reassemble the boats: 3,200 civilian staff (presumably to do the reassembly and support the rest of the staff), 500 sailors, 50 overseers, 5 scribes, and 1 man in charge of it all (Intefoker, of course). Trips to Punt could not and were not organized by private citizens for personal profit; they were simply too expensive. Trade with Punt was state initiated and state run, and the trade goods were intended for state and temple use.

It is clear that the people of Punt traveled to Egypt to trade. In one depiction, they arrive with raftlike boats with triangular black sails and large steering oars. The Egyptians are usually quite disrespectful of foreigners in texts and art, but in scenes where the Puntites visit Egypt and in the Hatshepsut inscriptions where her envoys visit Punt, relations between the two countries are very cordial.

—Vanessa Smith

River and were hunted by the Egyptians. But elephants did not live in the Nile Valley during the Dynastic period, and their tusks were much larger than those of the hippopotamus. Like ebony, ivory was mainly used in furniture by the ancient Egyptians and was a luxury good.

The Egyptians also traded for gold and electrum (a gold and silver alloy) from Punt. Egypt controlled gold mines in the Sinai, the Eastern Desert, and the Sudan, so gold from Punt probably just supplemented that from the state's mines.

The Egyptians brought back living animals and their pelts from Punt, the more exotic the animal the better. Texts and drawings show short-horned cattle (not a native Egyptian species), baboons, monkeys, dogs, foxes, ostriches, ibex, cheetahs, leopards, etc. These animals and their skins were not simply luxury goods but also curiosities to be marveled at by the Egyptians.

The ancient Egyptians also trafficked people. There are at least two references to Punt expeditions returning with pygmies, who were meant to dance for the gods in the temples. It is clear that the pygmies caused a sensation among the Egyptians. One letter from the young king Pepi II (Sixth Dynasty) states that the pygmy must be guarded very carefully to protect him from falling over the side of the boat on the return voyage from Punt. The Hatshepsut inscriptions

indicate that the Egyptians returned with some people of Punt and their children. It is unclear whether these people were slaves or immigrants, but given the good relations between Egypt and Punt, it is more likely that they were immigrants.

■ Introduction: The Sea Peoples

The Sea Peoples" is a term used to describe the mobile, displaced groups who were associated with attacks upon and disruptions of many societies around the eastern Mediterranean around 1200 BCE. They fell upon areas from Greece and the Aegean to Anatolia and Cyprus and as far as the Levant and Egypt. Their origins, movements, and actions were instrumental in the transformations that occurred in this region at the end of the Bronze Age and the beginning of the Iron Age.

Egyptian inscriptions provide key evidence for identifying the groups involved. Merneptah, the last significant pharaoh of the Nineteenth

Dynasty, and Ramses III, the second pharaoh of the Twentieth Dynasty, both recorded inscriptions that described their forces successfully defeating a number of groups, collectively called the Sea Peoples. Merneptah names Lybians and allied Sea Peoples, the Meshwesh, Sherden or Shardana, Lukka, Ekwesh, Teresh, and Shekelesh. Ramses III identifies a coalition of Peleset (the biblical Philistines), Tjeker, Shekelesh, Denyen, and Weshesh. Relief carvings depict Egyptian forces defeating these attacking groups in battles both on land and sea and also taking captives.

Further evidence for the Sea Peoples comes from archaeological excavations around the east-

ern Mediterranean basin. Heinrich Schliemann's excavations at the ancient Homeric cities of Troy and Mycenae in the late 1800s found a distinctive ceramic style that he attributed to a culture he called Mycenaean. Destruction layers at these sites marked the beginnings of the Greek Dark Age. Sir Flinders Petrie discovered similar Mycenaean pottery in tombs excavated in Egypt in 1889. Petrie was the first to suggest that this type of pottery might be evidence of a connection to the Sea Peoples and their Aegean origins.

In the early 1900s, excavators began to identify sequences of layers indicating that the Late Bronze was a period rich in trade throughout the eastern Mediterranean basin. Pottery manufactured in Mycenaean sites in the Aegean was discovered at sites in the Levant, Cyprus, and Egypt. The Bronze Age ended, however, with destruction at most of these sites. The subsequent period, the Iron Age, began without imports. At many sites, however, Early Iron Age pottery was manufactured from local clays while using the same shapes and decorative styles as the prior imported vessels.

The ceramic evidence together with new buildings, settlement patterns, and other artifacts suggest that the disruptions at the end of the Late Bronze Age were connected to the displacement of groups of Sea Peoples. The Iron Age began with Sea Peoples settling again not just in the Aegean but also together with local inhabitants at many places around the eastern Mediterranean. In Palestine, the Peleset, a Sea People group named Philistines in the Bible, became the coastal rivals of the Israelites.

- Sanders, N. K. *The Sea Peoples: Warriors of the Ancient Mediterranean, 1250–1150 B.C.* New York: Thames and Hudson, 1985.

Who Were the Sea Peoples?

The Sea Peoples were small groups not clearly associated with any one location or any of the major city-states that typified the Late Bronze

Age east Mediterranean world. The large city-states and empires were characterized by agrarian economies and united by long-distance trade. Various Sea People groups are named in texts produced by other civilizations and identified variously as seafaring traders, mercenaries, or invaders. These groups rose to greater prominence during the years marking the end of the Late Bronze Age. Texts from many of the city-states and kingdoms clearly associate the Sea Peoples with the upheavals that mark the end of the age.

Egyptian inscriptions explicitly call some of these groups Peoples of the Sea. Those specifically

named include Denyen, Shardana, Lukka, Meshwesh, Ahhiya, Teresh, Ekwesh, Shekelesh, Peleset, Tjekker, and Weshesh. Identity is largely discussed in terms of where the groups originated and how names of Sea Peoples correlate with groups named in other sources from both earlier and later periods.

It is likely that the Sea Peoples were involved in long-distance trade networks during the Late Bronze Age. Sea trade is reflected in similarities in the forms and decorative styles on pottery vessels and other artifacts recovered from archaeological sites throughout the eastern Mediterranean. These similarities imply that there were related groups of people who carried the trade. However, scholars remain uncertain about where many of these groups originated.

The Egyptians repulsed an invading force of Sea Peoples in the eighth year of the reign of Pharaoh Ramses III (ca. 1186 BCE). An inscription on the mortuary temple of the pharaoh at Medinet Habu proclaimed that people from foreign lands conspired to attack Egypt. A number of other areas were reported to have been attacked by the invaders prior to their appearance in Egypt: Hatti, Kode, Carchemish, Arzawa, and Alashiya. These names refer to a number of northern peoples and places: the Hittites of Anatolia (Hatti and Carchemish), the region of Cilicia (Kode), eastern Asia Minor (Arzawa), and Cyprus (Alashiya). This would suggest that the Sea Peoples originated in northern Mediterranean regions.

Earlier Egyptian inscriptions from the time of the Nineteenth Dynasty pharaoh Ramses II (ca. 1301–1235 BCE), whose forces fought against the Hittites in the Battle of Qadesh in Syria, support this northern connection. Included in the list of groups who fought alongside Egyptians in the pharaoh's army were the Shardana, Lukka, Derden, Masha, Pitasha, Arawanna, and Karkisha.

Merneptah, another Nineteenth Dynasty pharaoh, defended Egypt in the fifth year of his reign (ca. 1220 BCE) from attacks by a coalition of Lybians and allied Sea Peoples. The inscriptions celebrating the Egyptian victory list specific names of the attacking groups who were defeated: the Meshwesh, Sherden or Shardana, Lukka, Ekwesh, Teresh, and Shekelesh.

Ramses III repulsed a more serious Sea Peoples attack in the eighth year of his reign (ca. 1186 BCE). The same inscription on his mortuary temple at Medinet Habu, which described the attackers in northern lands, also reports in both words and relief carved images that his forces defeated a coalition of Peleset, Tjekker, Shekelesh, Denyen, and Weshesh.

A final piece of Egyptian evidence comes from a papyrus document written shortly after the death of Ramses III. It celebrates the victories of the pharaoh against foreign attackers. It refers to the Denyen, Tjekker, and Peleset and mentions the Sherden and the Weshesh as being from the sea.

Causes of the Movement of Sea Peoples

There are a number of possible reasons why the Sea People groups embarked on their journeys around the eastern Mediterranean. One suggestion is that they were displaced by other groups moving southward into northern Greece, the Aegean, and Asia Minor from eastern Europe. This is an older theory that is based on the assumption that most conflict and movements of people are rooted in a natural human tendency for territorial expansion and conquest. Sites in Greece such as Mycenae and Phylakopi suffered a series of destructions at the end of the Late Bronze Age. Subsequent occupation included pottery with styles similar to that found in the Balkan regions. This implied that these sites were destroyed by northern invaders from the Baltic area

who then occupied the destroyed sites and pushed the previous occupants, the Sea Peoples, out into the eastern Mediterranean, where they eventually came into conflict with other groups in eastern Asia Minor, Cyprus, Syria-Palestine, and Egypt.

Another idea is that the Sea Peoples instigated the aggression themselves. This theory supposes that because of growth in population or lack of resources, the Sea Peoples actively sought new territories and lands for new settlements. Their expansion led to conflicts that produced the destruction layers discovered by archaeologists at many eastern Mediterranean sites at the end of the Late Bronze Age. However, there is little evidence in Greek and Aegean sites to suggest that there was population pressure or resource depletion.

A third possibility is that there was a natural catastrophe that forced the Sea Peoples out of their home territories. A potential candidate for such a natural event is the massive volcanic explosion at the Aegean island of Santorini. However, this eruption occurred centuries before the end of the Late Bronze Age (and the migration of the Sea Peoples), and although it would have caused major disturbances in the lives of people in the Aegean at the time of the event, it is highly unlikely that this was the cause of the Sea Peoples movements.

However, the movement of Sea Peoples was most likely caused by the general economic collapse and upheavals at the end of the Late Bronze Age. The Egyptian reliefs thus may depict not invaders intent on destruction and domination but rather people displaced by the collapse of the economic system upon which they depended. In this case the Sea Peoples' journeys probably followed established trade routes. They may have been seeking to settle with well-known trading partners and thus traveled to a fruitful land they already knew, such as Egypt or the coast of Syria-Palestine. As long-distance traders, they were seeking new opportunities and new places to live as they attempted to continue trading in spite of the collapse of trade and economic networks upon which they depended. If this is the case, then the peoples depicted on the Egyptian reliefs could as easily be refugees as invaders.

➤ MYCENAEAN IIIC:1B POTTERY

Mycenaean IIIC:1b is the label for pottery characterized by a distinctive ceramic decorative style that was made in the Mycenaean world of Greece and the islands of the Aegean at the end of the Late Bronze Age. Mycenaean pottery, which was first identified as a distinctive type at the Greek site of Mycenae, developed through a number of stylistic variations in the Late Bronze Age. It was a valued trade commodity, manufactured in the Aegean world and then traded throughout the eastern Mediterranean in that time period. Mycenaean IIIC:1b, also known as the Close style, falls at the end of the era. It is characterized by a light cream-colored slip that was decorated with a concentrated variety of geometric and animal designs painted in a darker brown. The decoration was applied to a number of different vessel types.

At some sites, following the end of the Late Bronze Age and in levels immediately above destructions marking the end of the era, Mycenaean IIIC:1b vessels were made locally using local clays. This indicates the cessation of long-distance trade around the eastern Mediterranean and strongly implies that potters manufacturing the vessels were very well acquainted with the style and perhaps had migrated from Aegean settlements as part of the movement of Sea Peoples.

Travel Routes of the Sea Peoples

Determining the routes of the Sea Peoples' movement depends in large part on where the different groups originated.

➤ CONTROVERSY—BY LAND OR BY SEA

Scholars are divided on how the Sea Peoples migrated to the Levantine coast, by land or by sea. Obviously, there had to have been some travel over sea, but there is some evidence to suggest that the Sea Peoples landed in Egypt first and may have traveled over land to the Syro-Palestinian coast. The controversy centers on evidence from Egyptian relief carvings and on interpretations of the ceramic evidence recovered at excavations along the Syro-Palestinian coast.

Dramatic images on the walls of the mortuary temple of pharaoh Ramses III (ca. 1186 BCE) at Medinet Habu depict two different battle scenes. One panel describes a furious battle between Egyptian soldiers in oared vessels and invaders traveling in unoared ships. The accompanying text celebrates Ramses's victory and explicitly mentions the invaders as making a "conspiracy in their islands." Further evidence for seaborne attacks comes from a cryptic letter recovered in excavations at the ancient city of Ugarit on the west coast of Syria that reports the sighting of enemy ships.

However, in another panel on the temple of Ramses III, Egyptian forces are depicted meeting invaders in a land battle. The attackers are foot soldiers, charioteers, and what appear to be noncombatant women and children riding in ox-drawn carts.

Excavations at many Syro-Palestinian sites have also revealed two ceramic stylistic phases following the destructions of the Late Bronze Age. Initial interpretations of this evidence were that the two ceramic styles correlated with two waves of invaders, one by sea and one by land. However, the current view is that the changes in style were more likely the result of local innovation and that there were not two waves of invasion.

—D. Bruce MacKay

In Greece and the Aegean area it is possible that some East European peoples moved southward as the Late Bronze Age ended. However, although it is clear that there were a great many similar changes in the cultures of southeastern Europe and the Aegean at the end of the Late Bronze Age, the evidence is not unequivocal that

Europeans moved southward into Greece and the Aegean as the era ended. If there was southward motion it would have progressed generally from the Danube River valley southward through the Balkans into Greece and the Aegean Islands.

Another region of interest for discussing the routes of movement of Sea Peoples groups is Asia Minor. The Hittite empire of north-central Asia Minor also collapsed at the end of the Late Bronze Age, as is evidenced by destructions at the Hittite capital city of Khattusha, the site of Boghazköy in Turkey. Texts recovered in excavations there report conflict with the Kashka, who were likely located just to the north of Khattusha along the shores of the Black Sea. Other documents describe tensions with Arzawa and Lukka, which lay to the southwest along the Aegean coast. These documents would seem to indicate that apart from general turmoil, it is possible that there were movements of people southward from northern Asia Minor and eastward from the Aegean coast. There may also have been some movement northward from the Mediterranean coast against the Hittite heartland in central Anatolia.

Movement by groups on and across the Mediterranean ocean is another issue. Cuneiform letters have been discovered at Ugarit (Ras Shamra on the Syrian coast) that indicate that ships from Cyprus were involved in conflicts both with the Hittites and with Ugarit. Also, texts of the Egyptian pharaoh Merneptah describe attacks from Lybia that his army successfully defeated. Included with the Lybians are the Meshwesh, Shardana, Lukka, Ekwesh, Teresh, and Shekelesh. These groups are thought to have been coastal peoples from a variety of locations around the eastern Mediterranean. Since they were attacking Egypt from the west along the North African coast, they almost certainly crossed the Mediterranean southward from the Aegean or Crete.

Finally, the listing of names in the texts of Ramses III suggests a general north to south order of movement by the Sea Peoples. The report from the eighth year of the pharaoh's rule reports that no nation could stand before them, including Hatti, Kode, Carchemish, Arzawa, and Alashiya. The order of the cities implies a north to south movement.

However, although there is general consensus among scholars about the location of the named peoples in the Egyptian texts that describe the Sea Peoples, there is no clear unambiguous archaeological evidence for the routes of movements of any of these groups as the Late Bronze Age came to a close.

Medinet Habu

The great mortuary temple of Ramses III, known today as Medinet Habu ("City of Habu"), lies in Upper Egypt, near modern Luxor, along the southern edge of the ancient Theban necropolis. The ancient name of the site was Djamet and was the supposed burial place of the primordial Ogdoad of eight deities, who preceded the creation of the world. Although the main temple was constructed in Dynasty 20, under Ramses III (ca. 1198–1166 BCE), a number of subsidiary structures from both earlier and later periods are contained within its precincts. These include the so-called small temple, begun in the Eighteenth Dynasty by Hatshepsut (ca. 1502–1482 BCE), later usurped and expanded by a number of subsequent kings, as well as the chapels of the Divine Adoratrices of Amun, built in Dynasties 25 and 26 (ca. 755–525 BCE).

► CHAOS VERSUS ORDER IN THE RELIEFS

The battle reliefs depicting the victory of Ramses III over the Sea People horde effectively illustrate a very real threat to the established Egyptian order. However, the representation of the invaders as a tangled, chaotic mass of bodies also serves to associate them iconographically with the mythical forces of chaos. The motif of Egyptian order defeating foreign chaos appears again and again throughout the temple. The enormous outer gateway, or pylon, is decorated with colossal images of the king, poised to smash the skulls of bound captives. This image not only served as a self-explanatory political statement but also functioned to magically ward against all such foreign people. This type of imagery achieves its most blatant expression in the window of appearances, wherein Ramses would stand to greet assembled crowds. Here we encounter the smiting scene on either side of the window accompanied by smaller images of the king leading bound captives. Beneath these groups is a row of prisoners' heads, carved in high relief, that supports the platform above which the king would stand. As he stepped into the window, the king's physical presence would be magnified by his own colossal images, even as his feet trod upon the

severed heads of his foes, frozen in stone. The clear message of the pharaoh's invincibility, magically reenforced by his literal and symbolic trampling of the forces of chaos, would have been inescapable.

—Joshua Roberson

The bulk of the main temple has been reconstructed from thousands of fallen blocks and now stands as one of the most impressive such constructions from the New Kingdom. The copious reliefs preserved on the walls of the temple provide a vital glimpse into the ideological, military, and religious concerns that gripped Egypt in the latter half of the New Kingdom. From a historical perspective, some of the most important inscriptional material concerns Ramses III's famous conflict with the Sea Peoples. Already in the Nineteenth Dynasty, Merneptah (ca. 1237–1226 BCE) had repulsed an earlier incursion by groups of these eastern Mediterranean nomads. Some 33 years later, in his eighth regnal year, Ramses III weathered a second invasion, the results of which he immortalized in text and image. On the north wall of the main temple, Ramses is shown counterattacking the Sea People forces, which poured in over land and water; his army was ultimately successful against the former, while his navy defeated the enemy ships off the Delta coast. The images in the reliefs are staggering in their depiction of the chaos of these battles, showing countless foreign corpses speared like fish and cast headlong into the turbulent sea. Through their midst sail the high-prowed Egyptian war barges as archers reign down their deadly volleys, and the triumphant infantry leads bound captives away to be dispatched according to the king's whim. The lists of conquered peoples that accompany the reliefs provide some limited insight into the invader's identities. While some of these, such as the Peleset (Philistines), represent archaeologically or textually identifiable peoples, the specific origins of others remain speculative (e.g., the Denen, whom some scholars have identified as early Greeks) and must continue to be grouped under the general heading of "people of the sea," coined by Merneptah, following their initial invasion.

The Philistines and Hebrews

Biblical stories, especially in the books of Judges and in 1 and 2 Samuel, describe a conflict between the Israelites and Philistines. The Hebrew people, who are described expanding their sphere of influence out of the central hill country, meet resistance from the Philistine people who lived along the coast. Discussion of the history of these two groups has considered the question of origins and how the Philistines are connected to the Sea Peoples.

Apart from the internal biblical evidence, the clearest external evidence for the Hebrews comes from the fourteenth-century BCE Amarna texts recovered at the Egyptian site of Tell el-Amarna, the former capital of Pharaoh Akhenaten. These letters give a rich description of economic, social, and political contact between Egypt and various Late Bronze Age city-states in Syria-Palestine. The Hapiru, a label used for a mobile and disruptive group of people whom the kings of a number of city-states complain about, are likely early manifestations of the Hebrews, given the linguistically strong connection between Hapiru and Hebrew.

The biblical Philistines, again because of the linguistically strong connection, are almost certainly related to the Peleset named in a number of Egyptian sources that describe Sea People groups. The Egyptian pharaoh Merneptah defended Egypt in the fifth year of his reign from an attacking coalition of forces approaching across the North African desert from Lybia. Among the Lybian allies named are the Peleset. The famous Ramses III also names the Peleset in the list of attackers the pharaoh defeated, both on his mortuary temple at Medinet Habu and in the papyrus Harris. These texts suggest very clearly that the Peleset were one of the Sea Peoples.

The Philistines were located, according to the biblical evidence, around five main cities lo-

cated in the coastal plain: Ashkelon, Ashdod, Gaza, Ekron, and Gat, the so-called Philistine Pentapolis. The Philistines figure prominently in stories dealing with the early consolidation of Israelite identity and religio-political authority. Notable stories of this time include tales about the Hebrew hero Samson and his downfall at the hands of the Philistines and the Philistine woman Delilah (Judges 16:4–31), the loss of the Ark of the Covenant to the Philistines (1 Samuel 4), and the battle between the Israelites and Philistines in the valley of Elah where the hero David defeats the Philistine Goliath (1 Samuel 17). Although there is no way to confirm the historical veracity of these tales, collectively the stories depict clear differences and tensions between the Hebraic Israelites of the hill country and the coastal Philistines.

In terms of material culture, ceramic evidence from the early Iron Age excavated at the known Philistines cities of Ashdod, Ashkelon, Gaza, and Ekron demonstrates continuities with Mycenaean ceramic traditions from the Late Bronze Age and differences with the ceramic repertoire of hill country sites at this time. Fol-

lowing the Late Bronze Age destructions at these Philistine sites, locally made Mycenaean IIC:1b indicates continuity with Aegean ceramic traditions. The material culture thus adds additional weight to the argument that the Philistines were related to the Peleset of the Sea Peoples. Later ceramic traditions are characterized by a distinctive black and red, or bichrome, decoration, which has been called Philistine. The concentration of vessels of these types in coastal sites and their relative paucity in hill country sites overlaps with the biblical and extrabiblical evidence to suggest that the Sea People Peleset who settled along the coast were the Philistine rivals of the hill country Hebrews.

■ Introduction: The Exodus

Let my people go so that they may become my servants.” These words from the biblical book of Exodus have echoed throughout the ages, telling the story of the redemptive history of the ancient Israelites and their beginning in the land of Canaan. Exodus, an ancient Greek word meaning “going out,” is used as the title of the second book of the Bible and the second book of the Pentateuch. The story of the book narrates the story of how the ancient Israelites were released from the bondage of the ancient Egyptians into the hands of the Israelite national deity, Yahweh. Arguably the most important book for Jews and Christians alike, it is the story of the exodus that narrates the forging of a nation through the telling of a charter epic. The epic functions as the foundation story of the birth of a nation and the beginning of a narrative

theology of redemption and sanctification, two prominent themes in Judaism and Christianity alike. The events of this story resonate across time and space, so much so that the message and language of the biblical exodus have framed the origins of many modern-day liberation movements, from the civil rights movement of the 1960s to Zionist and liberation theologies of the twenty-first century. The story is of course retold yearly in the Passover Haggadah, and rabbis historically have reflected and interpreted these miraculous events of the crossing of the sea in both Midrash and Talmudic literature. Even Enlightenment discourse is preoccupied with this story, though in that time the emphasis shifted from God to Moses, emphasizing the memory of Moses in the book of the Acts of the Apostles: “And Moses was learned in all the wisdom of

the Egyptians and mighty in words and deeds” (Acts 7:22).

These retellings of the story remind us that the book of Exodus is a story of triumph against all odds. As a whole, the book of Exodus unites the rest of the message of the Bible, highlighting roughly five timeless themes: the sovereignty of God over nature, history as theological meaning, God as Creator-Redeemer, the institution and importance of religious rituals and practices for ancient Israel, and full release and liberation from slavery as a motive for social reform and covenant law.

There is little positive evidence for an actual historical event as described in the biblical account. Given anachronistic details in the Old Testament (such as references to camels before they were used in Egypt) and a lack of corroborative external evidence, most mainstream historians believe that the exodus account is a story of a later time period with minimal basis in historical events. Despite this, the story of the exodus is a profoundly important story for people throughout the world. The following entries examine the biblical story itself, some of the theories about routes of the exodus that can be reconstructed from the narrative, and other evidence that helps us understand this important tradition.

—Kevin M. McGeough

The Biblical Account of the Exodus

According to the biblical book of Exodus, the sons of Joseph, the Semitic official of the land of Egypt narrated in Genesis 41–47, grew in great number and settled in the region of Goshen of the Nile Delta after Joseph died. Joseph, the beloved son of Jacob, who was thrown into a well and sold into slavery by his brothers, had providentially risen through the ranks of administration throughout Egypt. But eventually his good fortune waned with the appointment of a new pharaoh to the throne, one who “did not know Joseph” (Exod. 1:8). By that time the Israelites had increased in number, so much so that their prosperity was considered to be a threat to the Egyptian way of life. Population control methods were introduced to limit the number of Israelites and minimize the risk of an Israelite revolt.

Egyptian taskmasters were set over the Israelites as they were enslaved in forced labor, building the supply cities of Pithom and Ramses. In an effort to rid Egypt of the next generation of Israelites, the pharaoh ordained a decree that all male Hebrew babies were to be exterminated. But the more the Israelites were oppressed, the more they increased and spread out throughout the delta, and the Egyptians hated them (Exod. 1:12). In resistance to a decree that would exterminate a new generation of Hebrews, a mother from the tribe of Levi placed her three-month-old baby boy, Moses, into a basket lined with tar and pitch along the Nile reeds. Moses, meaning “to be born” in ancient Egypt and a name also derived from the Hebrew root “to draw out,” was discovered by the daughter of Pharaoh and taken into the palace to be adopted into the royal nursery, to be trained in all of the wisdom of the ancient Egyptian court.

Unfortunately, the biblical account is silent and does not provide a historical biography of young Moses living in Egypt. It does, however, record a few defining moments in his life: Moses killed an Egyptian whom he witnessed beating a Hebrew slave, fled Egypt and found refuge in the land of Midian, and married a woman of Midian and was employed as a shepherd by her father, Jethro, a priest of a tribe in Midian. It was during his time of grazing sheep that Moses witnessed the most wonderful yet terrifying site of the theophany of God. God, in the form of a bush aflame yet unconsumed (Exod. 3:1–22), appeared before Moses, addressing him by name. Moses, who stood face-to-face before the God of his forefathers, Abraham, Isaac, and Jacob, heard directly from the God of Creation, whose special name was YHWH. It was this important event that inaugurated a dramatic turn of events in the life of Moses, as he then returned to his people, the Hebrews, and stood as the leader of the ancient Israelite ordained by Yahweh.

Upon returning to Egypt, Moses witnessed even harsher measures of enslavement on his people. Because of a strong disability with his mouth, he was accompanied by the Levite Aaron, who was appointed by God to serve as the mouthpiece of Moses, to stand before Pharaoh. Moses requested that the king of Egypt release the Hebrew slaves so that they could worship this

deity Yahweh in the wilderness for a few days, but Pharaoh refused to grant a holiday for a cultic festival. Consequently, Pharaoh received a visitation of ten plagues sent by Yahweh himself through the very hands of Moses, who now served as the prophet of his God and the prophet par excellence of all of Israel. Pharaoh eventually relented upon the receipt of the last plague over Egypt, the death of the firstborn in all of Egypt sent by the destroyer; however, the Hebrews who sacrificed the blood of a lamb and brushed it around their doorposts were saved, and the Israelites began their departure out of Egypt and away from Ramses. Pharaoh's heart was hardened by God, and he quickly engaged his chariots and horses to destroy the Israelites. The Israelites marched to Succoth and beyond and found themselves flanked by the Red Sea on the one side and the Egyptian army on the other side. In a miraculous movement authored by God, the Israelites were instructed to advance into the sea. The waters parted, the Israelites crossed over on dry ground to the other side of the shore, and the Egyptian forces who followed were destroyed halfway as the waters returned to the sea. There, Moses and Israel, free at last, sang a Song of the Sea in praise of God, and Miriam led the women in a dance (Exod. 15:1–21). These events were recorded and memorialized in the second book of the Bible.

Whereas the first part of the book focuses on the redemption of the people, the remainder of the book of Exodus narrates the sanctification of the Israelites through the giving of the law on Mount Sinai, the regulations of the institutions of royal cult and worship liturgy, the difficulty of their wanderings in the desert, the giving of divine provisions of food and water, and the building of a tabernacle to house God temporarily during their journey. Toward the end of the book, the composition of the Book of the Covenant (Exod. 20:22–23:33) forms a very prominent section of the book of Exodus. The context of the covenant as a metaphor between God as sovereign king and Israel as a loyal vassalage, modeled after Near Eastern vassal treaties, is set during these formative and struggling years in the wilderness. The Mosaic covenant between God and Israel forms the basis for the rest of the Bible including the historical, wisdom, and pro-

➤ THE SONG OF SEA

One of the earliest writings of ancient Hebrew poetry, Exodus 15:1b–18, or what is known as the Song of the Sea, declares the victory of Yahweh over the mighty ancient Egyptians. Biblical scholars date the poem to the early thirteenth century BCE based on its archaic verbal forms and its structural similarities with poems from the Canaanite tablets of the Late Bronze Age city-state of Ugarit. The poem is preceded by a later narrative version of the account in Exodus 14.

In the Song of the Sea, like other older poems of the Bible such as Judges 5 and Habbakuk 3, Yahweh is depicted as a storm god who wields the forces of the nature with his mighty right hand to win the battle for the Israelites. In this case, the battle is recorded as Yahweh's battle over the forces of chaos embodied by the sea, similar to other ancient Near Eastern accounts of gods defeating the sea (see Marduk versus Tiamat in the Mesopotamian *Enuma Elish* and Baal versus Yam in the Ugaritic *Baal Cycles*), and he is given the ultimate victory, praise, and admiration for the Israelite defeat of Pharaoh's famed charioteers.

"I will sing to Yahweh, for he has triumphed
gloriously;
Horse and rider he has thrown into the sea (v. 1)
Yahweh is a warrior
Yahweh is his name (v. 3)
Your right hand, O Yahweh, glorious in power—
Your right hand, O Yahweh, shattered the enemy.
(v. 6)
At the blast of your nostrils the waters piled up,
The floods stood up in a heap. (v. 8)
You blew with your wind, (sea) covered them
(v. 10)."

—William Zimmerle

phetic literature, which all organically recall the covenant stipulations and the redemptive story.

Archaeological Evidence for the Exodus

The dating of the exodus is a contentious matter, but tradition places the event in the reign of Ramses II (ca. 1290 BCE), though the name of the pharaoh in the book of Exodus is omitted. This is one reason why archaeologists and biblical scholars alike have also expressed difficulty fitting the exodus narrative, especially the first 15 chapters, into ancient Near Eastern history. Although it is true that the biblical writers were

concerned with writing a theological history and not with an objective record of scientific facts in our modern sense, there is still little direct evidence in the archaeological record to date that supports the biblical account; nevertheless, the absence of evidence is not always the evidence of absence. What is the evidence, then, that provides a historical background for the plausibility of such an account? There is little direct archaeological evidence. Asiatic slaves with Semitic names serving in Egypt are mentioned in papyri, therefore attesting to slavery in the delta. Furthermore, excavations in the Sinai have confirmed an Egyptian presence through an extensive network of forts throughout the Sinai peninsula that correspond to the historical geography of Canaan listed in Exodus. However, given the paucity of the evidence, it cannot be stated that there is positive archaeological evidence to support a historical exodus.

—William Zimmerle

➤ MERNEPTAH STELE

The first nonbiblical attestation of Israel in the archaeological record is the Merneptah stele. Dated to circa 1207 BCE, the stele recounts the campaign of the Egyptian king Merneptah in Canaan against the enemies of Egypt, which in this case are the cities of Syria-Palestine: Ashkelon, Gezer, and Yanoam as well as the lands of Hatti, Canaan, and Hurri and the people of Israel. Here Israel is listed among other important entities, so it must have had considerable influence by this point to be on par with major city-states of the day, such as Ashkelon and Hurri.

Ancient Egyptian hieroglyphs are frequently written with determinatives that describe the category of words. In the Merneptah stele, the word "Israel" is listed with the hieroglyphic determinative of a people and not a city-state. Scholars believe that the attestation reflects Israel as a masculine collective with a patriarchal ancestry, a tribe and not yet a state. The Merneptah stele historically anchors the Israelites as a significant powerful patriarchal people by circa 1207 BCE on their way into the Promised Land.

The Route of the Exodus

The geography of the exodus is listed in the book of Exodus as a series of itineraries (see Num. 33:1–49, Num. 21:10–20, Deut. 10:6–7). The toponyms, or site names, point out where the Israelites stopped in the journey. Approximately three dozen locations are named, although none of the places listed can be found with certainty. Today, the city of Ramses, the starting point of the journey, is usually identified with Per-Ramses,

the delta capital of Egypt. Based on comparative linguistic evidence, Succoth is probably the Egyptian Tjeku. Kadesh-Barnea is probably Ain el-Qudeirat, a fertile oasis in the northern Sinai situated at the crossroads between two routes in the Arabian peninsula.

The mountain of God, known interchangeably by two appellations, Horeb or Sinai, has not been found. Traditionally, of course, the site is located where St. Catherine's monastery resides in the southern Sinai peninsula, but there is no concrete evidence to suggest that this is the same site besides the circumstantial evidence that the mountain is the tallest peak in the southern desert. The site was designated as the mountain of God in the Byzantine period.

Controversy still remains over the miraculous travails through the Red Sea. First, the Greek version of the Bible, the Septuagint, translates *yam suf* as Red Sea, while the Hebrew Masoretic renders it Reed Sea. Strong arguments support both renderings, but then a problem remains in the archaeological reconstruction of the event itself. Did the crossing occur at the shallow reed beds located in the northeastern Nile Delta or at the Red Sea? Did it happen at the thin strip of land near the Mediterranean coast at Sabkhat el-Bardawil (Lake Sirbonis)? No consensus exists among contemporary scholars, and the reconstructions are basically conjecture.

Generally, archaeologists reconstruct two geographical routes for the exodus, including the southern route through the Sinai and a northern one along the Mediterranean. Although the northern route would have been the shortest distance between the two points—Egypt and Canaan—it was avoided, as suggested by the anachronistic insertion into the narrative ("the way of the land of the Philistines" was not taken, Exod. 13:17–18).

Although the geography of the exodus itinerary is difficult to reconstruct, recent archaeological work in the Sinai has suggested two alternative routes, tracing four major east-west ancient routes running through the Sinai. Whereas the northern route runs along the Mediterranean coast, the other three routes run along the desert wadis, where water and trade routes were found. Most of the ancient settlements in this region were found in the south-central Sinai.

Despite the evidence offered above, direct historical-literary witnesses from the ancient Near East to these events are lacking in the archaeological record. But extensive excavations in the Sinai are limited due to environmental conditions. Nevertheless, archaeological surveys and small-scale excavations, such as the recent excavation of the site of Tel el-Borg, have revealed a systematic layout of fortified New Kingdom military checkpoints throughout the Sinai along the route known as the Way of Horus. In addition to more recent evidence, older data from excavations at Serabit el-Khadim in the early twentieth century revealed an Egyptian temple to Hathor and turquoise mining activities throughout the New Kingdom. The most striking evidence found there was the discovery of an early Semitic alphabet, adapted from Egyptian hieratic script and dating to circa 1500 BCE. More recently, rock inscriptions from the western desert of Egypt, a site in the Wadi el-Hol, have revealed even older evidence of an early Semitic alphabet dating to circa 1900–1800 BCE. Both of these finds attest to Semites living and working in Egypt and the Sinai Peninsula.

While concrete evidence does not currently exist for an exodus, historical analogs from the ancient Near East do supply us with knowledge of the migration patterns of Asiatics, or Semites, from Canaan into the Delta. Artistic reliefs of the Aamw, the Egyptian term for Asiatics, in the second millennium were found in the nineteenth-century BCE tomb paintings of Asiatics traveling into Egypt from Canaan in the tomb of Beni Hassan in Middle Egypt. Easily recognizable by their clothing and beards, the Asiatics in the Beni Hassan reliefs are nomads traveling from Canaan as part of the caravan trade into Egypt. This evidence attests to the migration patterns of the patriarchs from Canaan to Egypt during the Bronze Age and concurs with the literary picture of the patriarchs in the book of Genesis providing plausibility to a biblical account of an Israelite exodus out of Egypt.

■ Introduction: The Issue of the Conquest and Settlement of Canaan

The conquest of Canaan is a term used to describe the biblical narrative of the forceful occupation of southern and central Palestine by the ancient Hebrews. According to the biblical story, after the ancient Israelites escaped from Egypt and wandered for 40 years in the wilderness of the Sinai, Moses stood upon the mountain of Nebo in Transjordan overlooking the entire land that was promised to his forefather, Abraham, and died. Moses, forbidden by God to enter this new land (Deut. 32:48–52), was succeeded by Joshua (son of Nun), who led the Israelites across the Jordan River in divine campaigns against the powerful city-states of Canaan to fulfill their national destiny. Largely successful in warfare because of their obedience to God, the Israelites marched from one victory to another, commanded to seize and settle down to build their homes in the Promised Land of their forefathers, a land that is described in the Bible as a "good and spacious land, a land flowing with milk and honey." Biblical scholars and Near Eastern archaeologists debate the nature and date of the occupation of this land and the historicity of the biblical tradition. The following entries compare the biblical and archaeological evidences for the emergence of Israelite settlements in Canaan and pay particular attention to the problems of history, geography, social lifestyle, and communal structures of ancient Israel in the Iron I period (1200–1000 BCE).

Biblical Evidence—The Conquest Narratives (Joshua and Judges), 600 BCE

The biblical books of Joshua and Judges provide the historical accounts for the conquest and settlement of Israel in the highlands of Canaan during the twelfth and eleventh centuries prior to the United Monarchy. Although the books were probably written by one historian, the books differ in their treatment of the period, in large part because of the sources that were available to historians, including oral traditions and written documents, and the unique theological message that each book carries. The first of these books, the book of Joshua, is the sixth book of the Old Testament and the first of the historical books. Written by the Deuteronomistic Historian (DH), it was composed of 24 chapters, divisible along four thematic lines: the introduction of Joshua, son of Nun, as the new leader of the tribes (chapter 1); the conquest of the cities of Canaan (chapters

2-12); the distribution of the land among the tribes (chapters 12-22); and the concluding words of Joshua upon his death (chapters 23-24). The latter book mentioned, the book of Judges, immediately follows the book of Joshua in the order of the biblical canon. It is divisible along three thematic lines: the introduction of the period of the Judges in Israelite history (chapters 1-3), the summary of events under the five great judges as well as a few minor ones (chapters 3-16), and the appendices, a few stories that describe the historical period at the start of the book of Judges in chapter 1.

The core of the book of Joshua is the theological motif of divine warfare. Joshua 10:24 declares the message perspicuously as a statement that serves as a reminder of the reason for this national epic of a miraculous conquest under one leader: "The Lord fought for Israel." Beginning with the transfer of leadership from Moses to Joshua in chapter 1 (verses 1-18), the first two chapters of the book of Joshua focus on the divine commandments and promises, (1:1-9), principles for successful campaigning when in the Promised Land. The literary design of the depiction of the battles themselves are presented with an economy of words, emphasizing the swiftness of the victories as it describes the Israelites crossing the Jordan River (2:1-9:27), attacking central Palestine, sweeping through the southern cities of Palestine (10:1-43), and finally defeating the northern cities of Galilee (11:1-23). Jericho is recorded as an unconventional and mighty victory (5-6) with parades and trumpets, followed by the city Ai, but only after Achan is punished for violating the covenantal principles and seizing booty that belongs to God (7:1-8:29). Chapters 3-5 narrate in detail the unification of the Israelite tribal confederacy with the renewal ceremonies at the sites of Gilgal and Shechem. Chapters 6-12 list the conquest of the Canaanite city-states, in particular Jericho (12:9), Ai (12:9), Jerusalem (12:10), Hebron (12:10), Jarmuth (12:11), Lachish (12:11), Eglon (12:12), Gezer (12:10), Debir (12:13), Geder (12:13), Hormah (12:14), Arad (12:14), Libnah (12:15), Adullam (12:15), Makkedah (12:16), Bethel (12:16), Tappuah (12:17), Hepher (12:17), Aphek (12:18), Lasharon (12:18), Madon (12:19), Hazor (12:19), Shimron (12:20), Achsaph (12:20), Taanach

(12:21), Megiddo (12:21), Kedesh (12:22), Jokneam (12:22) Dor (12:23), Goiim (12:23), and finally Tirzah (12:24). The final chapter of the book of Joshua recounts Joshua's last address to the Israelites as he further unites the tribes in their loyalty to Yahweh alone. Not all of Canaan was conquered in this major offensive, but Israel obtained a good foothold in the land and ultimately was fashioned and formed in preparation for its transformation from a tribal polity to a nation under King David in circa 1000 BCE.

Whereas the DH in the book of Joshua narrates the events as a blitzkrieg—or a lightning-speed victory from the east to the west, from Ammon to the hill country of central Canaan and the north to Galilee—the DH in the biblical book of Judges weaves together multiple accounts and offers a slightly alternative tradition of settlement that reflects a slower and more gradual infiltration of the Israelites into the Promised Land. In the latter book, the DH narrates the literary and theological themes of covenant and community through the social and religious struggles of idolatry, divine punishment, and divine aid. The book of Judges narrates the emergence of a new office for the Israelite community, the *shopbet*, a Hebrew term that denotes charismatic rulership and means "judge," or one who takes a particular centralized rule in the military and administrative-legal functions of the community. Judges, in ancient Israel, had the unique ability to discern the times, and they offered their voices to reinforce the old covenantal ideals of Sinai, ideals essential to the tribe's communal cohesiveness in times of crisis.

Although both books of the Bible, Joshua and Judges, record at times the common identity of the Israelite tribes, the book of Judges, however, largely offers a more nuanced narration into the various conflicts of the tribes and the social crises of the day. According to Judges 21:25, "In those days, there was no king in Israel; all the people did what was right in their own eyes." The task of making right in the land was set to judges who are named, and their actions are reviewed in the book, beginning with Othniel, Ehud, and Shamgar (chapter 3); Deborah and Barak (chapters 4-5); Gideon (chapters 6-8); Abimelech (chapter 9); Jephthah and minor judges (chapters 10-12); and the great judge Samson

(chapters 13–16). In these chapters, the book often juxtaposes themes of strong versus weak judges in its structural organization. But redemption was possible even for the weak judge, and although Samson is often interpreted as a tragic hero, a strongman who falls prey to his own weaknesses, he indeed renewed his vow to God, overcame his tragedy in the end, and recovered his virtue in one last feat of strength against the Philistines.

In Judges chapter 5, the hallmark of the biblical book of Judges, there is an ancient Hebraic poem that has its roots in oral verse. This ancient poem, called the “Song of Deborah,” serves as an eyewitness account of God’s victory in battle and follows the narrative counterpart in Judges chapter 4, which sets up in detail the Israelite campaign against the kings of Canaan under the leadership of the judge Deborah and the commander Barak. In the victory ode of Judges chapter 5, the tribes of Ephraim, Asher, Zebulun, and Issachar answer the call to battle the Canaanite king Jabin, while Reuben, Dan, Asher, Zebulun, and Naphtali refuse to follow and face rejection and ridicule. Judges chapter 5, then, provides the biblical interpreter with unique insight into the theopolity of tribes, who did not always operate in accord, offering a more complex picture than the book of Joshua on the nature of the individual identity of the collective tribes and the role of the judge as military leader of the community.

The Archaeological Evidence for the Settlement of Canaan

The archaeological problem of the conquest and settlement of the ancient Israelites rests in part on the dating of the events themselves. Some contemporary archaeologists have followed the interpretations of the ancient Jewish historian Flavius Josephus and have placed the departure of the ancient Israelites from Egypt in the time of the Egyptian purge of the mighty Hyksos from their capital at Avaris in the Egyptian Delta region. According to a literal reading of the biblical account, specifically 1 Kings 6:1 (“And it came to pass in the four hundred and eightieth year after the children of Israel had come out of the land of Egypt, in the fourth year of Solomon’s reign over Israel”), Israel would have left the land of Egypt around 1446 BCE and entered Canaan 40 years later. The conquest then would have taken place in the 15th century between around 1406 and 1400 BCE. Given the close proximity of circa 1446 BCE to the date of the Egyptian pharaoh Ahmoses and his purge of the Hyksos from Egypt to Sharuhén in circa 1550 BCE, an Israelite connection with the Hyksos is plausible, although these foreign rulers of the Delta were never described or depicted as slaves, as indeed the Israelites were. More problematic, however, is the fact that if this chronology is accepted, the period of conquest and settlement is much longer than the current archaeological record for occupation of the various Canaanite cities supports. Additionally, the only extrabiblical evidence for Israel as a tribal people exists on the Merneptah stele inscription that dates to circa 1207 BCE. Thus, contemporary scholarship emends the date of the conquest roughly to the thirteenth century BCE, an emendation dating from the days of William Foxwell Albright, the father of biblical archaeology, who based his date on the excavations of four important archaeological sites: Tell Beit Mirsim (which he thought was biblical Debir), Beitin (possibly biblical Bethel), Lachish, and Hazor.

The thirteenth and twelfth centuries in Canaan were a cosmopolitan period of a mix of ethnicities swarming throughout the land, many of whom the ancient Israelites would engage with militarily. Influxes of Sea Peoples arrived

Pillars partially unearthed at the archaeological site of Hazor. (Library of Congress)

from the Aegean by land and by sea, and they were depicted as new arrivals with their families on the temple walls of Medinet Habu in Egypt. Eventually defeated by the Egyptians, the Sea Peoples were relocated to Palestine, and the ancient Peleshets, or Philistines, settled in lower Palestine. The Peleshets would eventually build the cities of the Philistine Pentapolis in southern Canaan, cities that were renowned throughout the biblical world: Gath or Safi, Ashkelon, Ashdod, Ekron, and Gaza. The Philistines would bring Aegean cultural traditions to Canaan that would include the consumption of pork and wine and the cult worship of the Aegean mother goddess. Upon the disintegration of the Egyptian empire after 1153 BCE, the Philistines would spread out in all directions and threaten the Israelite settlements, a historical fact that is attested in the historiography of the book of Judges and throughout the book of 1 Samuel. The Philistines were a formidable foe, and their threatening presence convinced the Israelites to demand from God an earthly king to protect and rule over them (1 Sam. 8:5).

Although successful reconstructions of the Philistine occupation in Palestine are possible because of extensive excavations at the sites of the Pentapolis and clear ethnic markers such

as the great presence of pig bones in their archaeological record, reconstructions of Israel's emergence in the highlands are more difficult to support. According to Harvard archaeologist Lawrence Stager, in order to persuasively present a case for the mass migration of people from one homeland to another or to substantiate this unified conquest theory found in the book of Joshua, an archaeologist must be able to (1) trace the newly supplanted culture from its homeland or origin; (2) find the homeland of the migrating or invading group; (3) find discontinuities in the archaeological levels, such a massive destruction layers, if there was an invasion; (4) and trace the route of migration or invasion.

To date, there is inadequate archaeological evidence available for a unified conquest of Canaan that fits the criteria established above. According to the itinerary of the biblical conquest narrative in Deuteronomy and Joshua, the Israelites waged campaigns in Transjordan, seizing Heshbon, Sihon, Medeba in Ammon, and Dibon in Moab, taking the cities of Jericho, Ai, Gibeon, Lachish, Hazor, and Bethel by force as well as an itinerary of other less well-known sites. Archaeological excavations from these sites have yielded mostly weak data. From the biblical site of Jericho, for example, first excavated by the English archaeologist Katherine Kenyon, who was renowned for her stratigraphic methods, neither a large walled settlement nor destruction layers were found in the thirteenth century. One reason may have been the excessive erosion that the site has endured throughout the ages. Excavations at et-Tell, or biblical Ai, which means "ruin," revealed a large settlement, which was abandoned in the second millennium between circa 2250 and 1200 BCE. It resurfaced in the twelfth century with a new village planted there. Bethel, on the other hand, revealed a destruction level in the thirteenth century. And finally, ongoing excavations at Hazor, the head of all the cities listed in Joshua, have revealed strong evidence of a destruction level in the thirteenth century.

In summary, the problem lies in the fact that of about the 30 cities mentioned in the biblical itineraries of war, only 20 of the archaeological sites can be located to date. Of the 16 cities destroyed in Joshua, only 2—Hazor and Bethel—

yield layers of destruction in the archaeological record for the thirteenth century and support the first criteria listed above. (A third city is possible, but the verdict is still out on Lachish.) So, the archaeological evidence leaves scholars with many discrepancies and problems, and to date no current explanation reconciles all the loose data. Some attempts have been made to push the dating of the conquest even earlier than the thirteenth century to correlate with the biblical attestations of 1 Kings 6:1 or to relocate biblical sites such as Ai, but once again the archaeological issues are unresolved, and the verdict awaits further excavations and more thorough surveys in Israel.

Current Theories on the Conquest of Canaan

Biblical interpretation, particularly from the post-Enlightenment onward, has often emphasized contradictions in the biblical historical books and has subsequently tried to solve these discrepancies through the application of more empirically based historical and literary methodologies. In the German theological circles of the nineteenth and twentieth centuries, for example, emphasis was often placed on rereading the historical texts of the Bible less literally and more as etiologies, or causal narratives, oral stories circulating around the community that served the purpose of explaining local customs,

concepts, rituals, and important sacred places for reasons of tribal affiliation and communal identity. Given the rise of archaeology as a social science in the twentieth century, biblical scholars and Near Eastern archaeologists alike have more or less attempted to reconcile the textual data with whatever available archaeological data in three major ways. The first method was to read the text more literally, accepting the narration of the biblical text. The American scholar William Foxwell Albright and his student G. Ernest Wright supported this view, but they often overstated what the biblical text really said. The Albright-Wright synthesis, as it was called, also known as the conquest or military model, stressed the conquest narratives in Joshua and Judges as straightforward and reliable sources of historiography, detailing an accurate portrayal of the Israelite destruction of the Canaanite city-states. Albright, Wright, and the Israeli archaeologist Yigael Yadin were confident that the Deuteronomistic Historian's account was verifiable through the archaeological record. Yadin's excavations at Hazor and Tell Beit Mirsim, for example, also offered further evidence to support this hypothesis in its earliest stages.

Along with the first hypothesis mentioned above, a second hypothesis emerged out of the German form-critical school that is known as the peaceful-infiltration hypothesis. First formulated by Albrecht Alt, this second hypothesis rejected the notion of the Israelites as a wandering band of refugees from Egypt and used subsistence models, emphasizing their pastoral nomadic lifestyle in the central highlands. In a sense, Alt placed the narration of the book of Joshua after the book of Judges, stressing the notion of Israelite conquerors only later in their evolution as they began to settle and expand in number, forced then to defend their territory. For Alt, the Israelites were not outside invaders but instead were peaceful insiders who formed strong communities as a means of survival in the central highlands.

The final hypothesis purported to describe the theory of how the Israelites seized ancient Canaan was the peasant-revolt theory designed and defended by biblical scholar George Mendenhall. Mendenhall, later joined by Norman Gottwald, broke away from Albright's conquest

model and Alt's subsistence paradigm to suggest that the conquest was really an evolutionary revolt of indigenous peasant Canaanites fleeing toward more marginalized areas. In this sense, the Israelites were not a unique ethnic group but rather merely a subgroup of Canaanites, devoted to Yahweh, and broke away from their Canaanite overlords to establish communities in the central highlands.

These three classic arguments for the historicity of the settlement of Israelites in the central highlands have given way to more critical readings of the archaeological evidences that even stress less the unique phenomenon of how the early Israelites settled in Canaan. The last two decades of excavation work and surface surveys in the central highlands of Israel have revealed evidence that shows a dramatic increase in small farms and villages in the Iron I period. The Iron I settlements demonstrate a remarkably similar pattern of material culture that is evident of a mixed economy of sheep and goat herding and agriculture. Although many of these sites may point to Israelite settlements, they also may point to settlements of other Canaanite subgroups. The type of material culture found at these sites includes collared-rim storage jars; pillared houses; storage pits; faunal assemblages of sheep, goat, and cattle; and little or no pig bones. Such current data suggests, then, that ethnicity is difficult to detect in the archaeological record, and the Israelites were largely indistinguishable from the other communities of Canaan and the Transjordan.

The evidence for an explosion of population and settlement sites in the Iron I period has led contemporary archaeologists and biblical scholars to propose newer solutions to the conquest and settlement problems. For example, Israel Finkelstein and Neil Asher Silberman, who maintain in their recent and controversial book that there is no evidence for a violent invasion of in-

filtration or a migrating Israelite group, push a theory of settlement that emphasizes a revolution in seminomadic lifestyle as the explanation for how 250 hilltop Israelite settlements emerged in the highlands during the thirteenth century. Harvard archaeologist Lawrence Stager, on the other hand, offers a hypothesis based on ruralization instead of revolution as the means of explaining the deep structural changes of the settlement patterns at the end of the Late Bronze Age, when early Israelites who were becoming agriculturalists moved toward settling down beyond state control in the highlands and developed ways to terrace the land, store grain, and build cisterns and houses. The debates over the issue of how Israel settled in the Promised Land continue, and although it is difficult to locate a unique Israelite ethnicity in the archaeological record today, most if not all contemporary archaeologists and biblical scholars alike agree that Israel's ethnic identity is no doubt found in its uniquely religious phenomenon attested by their worship of and covenant with a very unique deity named Yahweh.

■ Introduction: Kassites

For over four hundred years, from around 1600–1155 BCE, Babylonia (in southern Mesopotamia) was ruled by a dynasty called the Kassites, a tribal people that most scholars presume came originally from the Zagros Mountain region. Under Kassite rule, Babylonia was both economically prosperous and politically stable. The rise and fall of this dynasty is obscure; historical records are somewhat lacking at both the start and the end of the Kassite reign. Despite the so called Dark Ages that bracket the Kassite period, much Babylonian literature survives from this period, in part because the Kassite kings sponsored Babylonian literature as a means of justifying their own rule. Not Babylonian themselves, the Kassites promoted Babylonian culture throughout the Near East and at this time the Akkadian language used in Mesopotamia became the language of correspondence between polities throughout western Asia, Egypt, and Cyprus. Thus, the Kassite period in Mesopotamia is of particular interest to world historians as this is a period when a foreign group gained control of southern Mesopotamia and promoted the spread of that culture throughout the Near East.

—Kevin M. McGeough

Kassite Babylonia

The Kassite dynasty of southern Mesopotamia ruled for about 400 years (1475–1155 BCE). This was not a period of complete calm, but both contemporary records and later tradition credit the Kassite kings with an unusually stable period of dominance. The origins of the Kassite are unknown, and it would be a mistake to think that the majority of Babylonia's inhabitants in this period were ethnic Kassites. The dynasty is given the name "Kassite" because of the distinctly Kassite names taken by most Babylonian kings in the latter half of the second millennium BCE. The Kassite kings adopted many of the trappings of Mesopotamian culture, including the languages and symbols of royalty, but they also adapted these elements to meet their needs. Babylonian

literature flourished over this long period. The latter half of the second millennium BCE was a particularly vital international period in ancient Near Eastern history when diplomatic ties were forged to avert wars and increase commerce. Archaeologists have discovered a number of settlements that date to the Kassite period in southern Mesopotamia. Some are known from earlier periods in Mesopotamian history, such as Babylon, Nippur, Ur, and Uruk. Other sites such as Dur-Kurigalzu appear to have been politically insignificant before the Kassite period.

The vast majority of the written sources about Babylonia in the Kassite period come from the major economic centers in the southern Mesopotamian city of Nippur and roughly date to the fourteenth and thirteenth centuries BCE. These are mostly economic and administrative documents as well as a number of letters. We know quite a number of titles and offices associated with the Kassite administration, but a very large sector of the workforce was servile. Only a fraction of the excavated sources have been properly studied by scholars. Unlike in the earlier Old Babylonian period (ca. 1800–1600 BCE), only a very few private contracts were found at the site of Ur, but most aspects of the private household economy do not appear in records from the Kassite period. Unpublished documents from the city of Babylon and elsewhere may one day shed light on domestic life in Kassite Babylonia.

A variety of types of personal names and group designations are attested in Kassite Babylonia. Only some of the personal names from this period are recognizably from the Kassite language, and many names are known from earlier and later periods of Babylonian history. Some scholars have argued for the multiethnic nature of Babylonian society in the Kassite period. In form this was likely the case. However, finding ethnicity in the archaeological record is difficult if not impossible, and the results of such attempts are often questionable or flawed. The textual record is useful because it allows us to attach names to different groups, but these names, like

➤ DUR-KURIGALZU

Dur-Kurigalzu (modern Aqar Quf), Akkadian for “Fortress of Kurigalzu,” is the ancient name of a major southern Mesopotamian settlement established by the Kassite king Kurigalzu I. Joint Iraqi-British excavators conducted archaeological investigations of the site during World War II (1942–1945). The king Kurigalzu who built Dur-Kurigalzu is the same one known from the Babylonian correspondence in the Amarna letters from Egypt. Even though the Kassite language is poorly understood, the royal name of Kurigalzu probably means something like “Shepherd (= Protector) of the Kassites.” Despite the fact that Kurigalzu undertook a major building project at Dur-Kurigalzu and renamed it in his own honor, there are indications that Dur-Kurigalzu was not an entirely new settlement in the fourteenth century BCE. During the fifteenth century BCE the name of the site was Parsa. Located just west of modern Baghdad and about 56 miles (90 kilometers) north of Babylon, Dur-Kurigalzu covers an area of about 556 acres (225 hectares). King Kurigalzu I commissioned a ziggurat, or temple tower, in Dur-Kurigalzu called Egirin (“Pure House”). Exposure to the elements over the millennia has weathered the ziggurat, but its core is still visible on the landscape to this day. In the sacred precinct around the ziggurat other temples were erected in honor of well-known deities from

the ancient Babylonian pantheon, such as Enlil, Ninlil, Ninurta, and Nisaba. We also know of a temple dedicated to the Kassite gods Shuqamuna and Shimaliya. Kurigalzu I had a palace built at Dur-Kurigalzu to which he gave a ceremonial, anachronistic Sumerian name meaning “Palace of the Whole World.” In the palace at Dur-Kurigalzu excavators found distinctive wall paintings of human figures in procession as well as terra-cotta sculptures, glass, gold jewelry, and other significant small finds. After the end of the Kassite dynasty in Babylonia in the twelfth century BCE, Dur-Kurigalzu was abandoned and never reoccupied.

Kassite, were the product of scribal activity and may not have reflected wider practices in ancient Mesopotamia. There are limits to what we can know about ancient attitudes. Personal names are a good example of this problem, since it is usually not clear why a certain personal name was chosen. The texts leave the impression that families in the Kassite period were organized in large kinship networks, called “houses.” Sometimes it is unclear whether the texts are referring to an actual house or estate or to a larger social group based around some idea of common descent. Scholars frequently describe these house-centered groups as “tribes,” but recent anthropological and ethnographic research has undermined commonly held ideas about what

tribes are in the ancient and modern Near East and elsewhere.

The diplomatic correspondence from the latter half of the second millennium attests to the active connections and competition among the neighboring rival powers of the day: Kassite Babylonia, Ramesside Egypt, Hittite Anatolia, Mittani in northern Syria, Middle Elamite in southwestern Iran, and eventually the Middle Assyrian empire. The Amarna letters mention the Kassite kings Kurigalzu I, Kadashman-Enlil I, and Burnaburiash II. Even though the dominant political figures had different ethnolinguistic origins, no attempt was made to fundamentally alter the dominant languages (Sumerian and Akkadian) and cuneiform script. Though it was not

the native tongue of any of the political entities of the day, Akkadian continued to be used as the international diplomatic language. Each of these political entities also cultivated local scribal traditions that preserved some elements of Mesopotamian scribal culture, but at the same time they also adapted cuneiform writing in innovative ways.

An innovation of the Kassite period was the creative use of cuneiform to commemorate economic activities using a new medium, called the *kudurru*. Kudurrus are a class of Babylonian documents, often in the form of stone monuments or smaller stone tablets that originated in the Kassite period. These inscribed objects document certain kinds of economic activities and relationships around concepts such as real estate, tax exemptions, temple service, and personal property. These objects are attested from the fourteenth century BCE up until the seventh century BCE, and some 160 individual pieces have been discovered. Although the term “*kudurru*” is often translated as “boundary stone,” there is very little evidence that these objects were used to mark property boundaries. Other than *kudurru*, there are few other Babylonian names for these objects, such as “stele,” “inscribed slab,” and simply “stone.” The archaeological evidence suggests that kudurrus were generally erected in or around temples or sacred quarters, perhaps to demonstrate divine approval of the economic relationships described in the inscriptions. Kudurrus were found in sacred contexts at sites such as Nippur, Dur-Kurigalzu, Babylon, Uruk, Larsa, and Ur. So far no *kudurru* has been found in situ, so only further scientific excavation can settle the question of where the ancient Babylonians displayed these objects.

The vast majority of inscribed material from Mesopotamia is preserved on clay, since stone had to be imported to Babylonia. The standard medium of the kudurrus, stone, was chosen for its permanence, since many of the inscriptions describe the documented economic relationship as being valid for all time. Although kudurrus commemorate a legal transaction, they were not simply legal contracts. In fact, some state that they were copied from clay tablets that acted as the proper legal document that could have been used in court.

These monuments are frequently decorated with distinctive divine symbols. These symbols can often be identified as specific gods in the Babylonian pantheon, and there is good reason to believe that the unidentified symbols also represented deities. We still do not understand the precise meaning and function of these elaborate symbols. Some scholars have attempted to view the symbols as representations of the constellations visible in the night sky. Others view the divine symbols as legal witnesses. Each theory has some merit, but the presence of the divine symbols may have been merely to secure the gods’ protection since a number of deities are invoked in the curses that constitute much of the final section of the text. For example, the curses on one text read:

“Should anyone violate the terms of the land grant, may (the sun-god) Shamash and (the storm-god) Adad, the mighty gods, the supreme judges, speak ill of him (in court) and may they not adjudicate for him a just and right verdict! May the god Ninurta, lord of boundaries and *kudurrus*, tear down his *kudurru*! May Gula, the great lady, place a chronic wound on his body, and may she bathe him in blood and pus as in water! . . . May the great gods named on this stele curse him with a wicked curse! May they rip out his foundation! May they annihilate his progeny!” [translated by author]

Kassite Origins

The Kassite dynasty ruled for centuries in southern Mesopotamia in the second half of the second millennium BCE, so it is something of a surprise that so little is known of Kassite origins. The Kassites first appear in Mesopotamian cuneiform sources in the early second millennium BCE. As with the Sumerian, Akkadian, Amorite, and Hurrian ethnolinguistic groups, hints of the Kassites presage their rise to power. Babylonia was probably not completely deserted after the fall of the first dynasty of Babylon (ca. 1595 BCE), but the details of the Kassites' movement into Babylonian society and subsequent rise to power are not adequately documented in the archaeological or textual records.

Scholars have long theorized about the origins of the Kassites as an ethnolinguistic group. The most plausible hypothesis at present is that the Kassites came down to the Mesopotamian floodplain from the Zagros Mountains in the north via the Diyala River basin. There are still questions about the Kassites' place in Babylonian society in the first half of the second millennium BCE. A certain number of Kassites were employed as workers or mercenaries in Babylonia toward the end of the first dynasty of Babylon in the seventeenth century BCE, but it is not likely that the Kassites were simply migrant workers in southern Mesopotamia. Unlike the Hittite invasion that destroyed the first Babylo-

nian dynasty, there is little evidence of a Kassite invasion. However, it should be noted that Kassite mercenaries sometimes sided with forces hostile to the kings of Babylon. In the eighteenth century BCE, kings Samsu-iluna and Abi-eshuh of Babylon reportedly defeated an army of Kassites. This is the first mention of the Kassites in the cuneiform record from Mesopotamia, but there are hints of Kassite personal names from previous decades. In a letter dated to the reign of Samsu-iluna, messengers from Aleppo to Babylon stop in a place called Bitat-Agum ("Houses/Families of Agum"), where the local leader bears a Kassite title. The second king of the Kassite dynasty was reportedly named Agum, but it is impossible to say where the settlement Bitat-Agum was located. It is also unclear whether this Agum ruled over a sedentary or seminomadic population.

Following these movements into southern Mesopotamia, at least some Kassites apparently integrated into Babylonian society. Some Kassites evidently assumed relatively high offices in institutions such as the military. However, other groups of Kassites evidently remained distinct in this early period.

► THE KASSITE LANGUAGE

Very little is known about the Kassite language. The Kassite name for Babylon was Karduniyash, and the Kassite word for “Kassite” was probably *galzu*. Not a single complete sentence of Kassite is preserved anywhere in the known corpus of cuneiform tablets. Attempts by some scholars to connect the Kassite language with Indo-Aryan are not convincing. The Kassite language is so poorly attested because of the Kassite dynasty’s thorough and systematic appropriation of Babylonian literature and culture. In addition, at no point in any period of Mesopotamian history were Kassites the majority ethnic group in Babylonia, which also might explain the continued reliance on the written Akkadian and, to a lesser extent, Sumerian languages.

The very first evidence for the Kassite language is indirect and dates to well before the advent of the Kassite dynasty. In the latter half of the seventeenth century BCE, there is mention of a translator who came from the houses (or tribes) of the Kassites to communicate with Babylonian military forces. It is reasonable to suspect that the translator was translating from Kassite into the Old Babylonian dialect of Akkadian.

There are three major types of sources that give direct evidence about the Kassite language: ancient glossaries, personal names, and individual words that were borrowed into Akkadian, the Semitic language used throughout Mesopotamia in the second millennium. There are only two ancient glossaries that shed light on the meanings of a few Kassite words. Neither glossary was produced by native speakers of Kassite. Rather, these glossaries are copies from a much later time (mid-first millennium BCE) of words that scribes needed to learn how to write and understand. The first Kassite glossary appears in a list of personal names that were then translated into Akkadian. The section that deals with Kassite names oddly begins with Hammurabi and Ammisaduqa, two kings from the First Dynasty of Babylon that preceded the Kassite period; both of their names are

Amorite, not Kassite. The other glossary contains Akkadian glosses of Kassite god names, titles, and basic vocabulary. The two generally agree, but this is no guarantee that together they adequately represent the Kassite language of the second millennium BCE. In fact, one glossary may have been created using the other.

A handful of Kassite personal names are known from the eighteenth century, and many more royal and personal names are attested later on throughout the second millennium BCE. Because it was first created to write Sumerian and then later adapted to write Akkadian, the Mesopotamian cuneiform writing system was inadequate for representing the sounds and structure of Kassite words and names. This should come as no surprise to anyone who has struggled to use one language’s preferred writing system to express the sounds in another language. For example, imagine trying to render Chinese names with the Latin or Cyrillic alphabets or Arabic names with the Korean syllabary.

One important by-product of contact between different cultures occurs at the level of language borrowing. Every language borrows and adapts words and phrases to enrich its vocabulary, and the peoples of ancient Mesopotamia were no different. A number of words in the Akkadian vocabulary appear to derive from Kassite. Many of these words refer to horses and various technologies associated with horses, but this should not be taken as an indicator that the Kassites were first and foremost master horsemen. Rather, such terms entered the Akkadian vocabulary in a haphazard way to meet specific needs at a variety of specific times.

Kassite Appropriations of Babylonian Literature

The Kassite period in Mesopotamia is also commonly called the Middle Babylonian period. In some ways the latter designation is more apt, since very little of the Kassite language and culture are preserved in the written record of cuneiform documents. Just as Egyptian culture appealed to foreign dynasties, subsequent Mesopotamian dynasties were quick to adopt many elements of Babylonian culture.

Although there are admittedly gaps in our knowledge of the literary activity from this period in Kassite Babylonia, evidence from Nippur and Babylon suggests that a widespread standardization of cuneiform literary traditions occurred at this time. Many of the texts relating to Mesopotamian omen science, including hepatoscopy, were edited and standardized in the Kassite period. This process may have had royal oversight, since there is at least one example where a text was produced for the Kassite king Nazi-Maruttash (1307–1282 BCE). Mesopotamian medical collections of prescriptions, diagnoses, and prognoses were compiled at this time as well. Literary works like the Epic of Gilgamesh and Enuma Elish likely took shape, and a large body of new Akkadian-language wisdom literature developed. There is some evidence for the educational process used to teach cuneiform in the Kassite period, but the documentation is much less rich than that of the preceding Old Babylonian period (ca. 1800–1600 BCE). Many elements of Old Babylonian scribal tradition were continued and enhanced in the Kassite period. This process gave rise to groups of Kassite-period scholars who examined and edited much of the cuneiform literature that is so abundantly attested later in the first millennium BCE. In the first millennium elements of the learned elite became so interested in scholarly pedigree that they frequently traced their origins all the way back to ancestors in the Kassite period. For example, some first-millennium scholars trace their genealogies back to Sin-leqi-unninni, who was credited with organizing the Epic of Gilgamesh. Although he does not have a Kassite name, Sin-leqi-unninni probably lived at some point in the mid-second millennium BCE.

One theme unique to the literature of the Kassite period is a general pessimism about the human condition. In the following example from “The Dialogue of Pessimism,” the word for “ruin-mound” is the same word archaeologists use today, that is, “tell”:

“Ascend the ancient ruin-mounds and walk around!
Look at the skulls of the lowly and the preeminent!
Which belongs to someone who did evil and which belongs to someone who did good?”

Another text, “The Babylonian Theodicy,” is somewhat reminiscent of the biblical Book of Job. The elaborate poetry of the Babylonian text is an acrostic, which means that the first sign of each stanza together form a phrase, in this case “I, Saggil-kinam-ubbib, the exorcism-priest, am one who blesses the gods and the king!” A poem known in Babylonia as “I will praise the lord of wisdom” describes the extensive suffering of its unnamed author, who appeals to the lord of wisdom, the god Marduk, for help.

Babylonian literary texts from the Kassite period have been found at Nippur, Babylon, and elsewhere. Many texts that were probably first composed in the Kassite period survive in later copies from the first millennium BCE. Although Sumerian literary texts are much more common in the Old Babylonian period, many continued to be copied and studied in the latter half of the second millennium BCE. Kassite kings also continued the tradition of having royal inscriptions written in Sumerian, such as Kurigalzu I’s inscriptions from Dur-Kurigalzu, as well as in Akkadian.

Other Kassite innovations took place in the manufacture of cylinder seals. Changes occurred in both the imagery and inscriptions on the seals. Unlike inscribed seals from earlier periods, inscribed Kassite cylinder seals often refer to more than just the bearer’s title. Parallels to these inscriptions are more readily found in the corpus of Mesopotamian literature than among administrative tools of the late third and early second millennia BCE. One Kassite period cylinder seal inscription is in Sumerian cuneiform and reads:

➤ ENUMA ELISH

Enuma Elish is the ancient title of an Akkadian-language composition written in the Mesopotamian cuneiform script. Sometimes referred to as the Babylonian creation myth or epic, *Enuma Elish* recounts the creation of the cosmos and the elevation of the chief god of Babylon, Marduk, to the head of the whole Babylonian pantheon. In the Assyrian version of *Enuma Elish*, Assyrian scribes replaced the name Marduk with the name of their chief god, Assur. The title *Enuma Elish* is what scholars call the composition's incipit, a term that refers to the very first phrase of a text: "When on high (Akkadian: *enuma elish*)," short for

"When on high the heavens had not been named,
Down below solid ground had not been called by
name . . ."

For a more familiar example, imagine if Shakespeare's *Romeo and Juliet* were referred to as "Two households, both alike in dignity," instead of by the names of two of its main characters. Referring to a composition by its incipit was a common practical shorthand throughout ancient Mesopotamia.

At the beginning of *Enuma Elish*, various gods are created from the commingling of the primordial fresh waters, personified as the god Apsu, and the waters of the sea, personified as the goddess Tiamat. Eventually the heroic god Marduk combats and defeats Tiamat. Marduk then creates the cosmos out of Tiamat's corpse. Scholars frequently compare elements of *Enuma Elish* and the biblical

creation motifs in Genesis and elsewhere in the Bible. One title that Marduk often bears is Bel, literally meaning "Lord" but also connoting "storm-god." Marduk's creation and ordering of the universe includes creating divisions of time (for example, the phases of the moon as well as the seasons), setting the fixed stars as constellations in the night sky, and the creation of temples for various other gods in the pantheon. From Tiamat's eyes, Marduk is said to have created the Tigris and Euphrates rivers, the very lifeblood of Mesopotamian civilization. Using the blood of Tiamat's henchman, Qingu, Marduk creates human beings. Marduk also founds Esagil, Marduk's main temple in the city of Babylon, as the center of the universe. The composition concludes with a series of exultations of Marduk, each of which addresses him with one of 50 different esoteric names.

Most of the tablets that preserve *Enuma Elish* are from the first-millennium BCE library of Ashurbanipal in Nineveh, but the text was probably composed sometime during the second millennium BCE. From the later first millennium BCE we have textual evidence of some of the most important public ritual activities in Babylonia. One such tablet gives a description of the Babylonian New Year's festival at which, we are told, *Enuma Elish* was publicly recited.

—Matthew T. Rutz

[All translations by author from the original cuneiform.]

"May he be established as one chosen by his god!
May he be considered noble in his king's palace!
As his lot may abundance, wealth,
and a long life be decreed for him!"

At the time this seal was produced, the Sumerian language had not been spoken for over half a millennium, and this type of Sumerian personal prayer for well-being is unknown before the Kassite period. Although the Kassites adopted much of the Babylonian culture that preceded their rule, they did embark on some subtle innovations within the bounds of the received tradition. The individual prayer on a cylinder seal, especially in Sumerian, is unique in this respect. As in the

present seal, various deviations from classical Sumerian are evident, such as the reinterpretation of the grammar, usage, and vocabulary of the long-dead language. Other seal inscriptions are better classified as psalms, since they merely exult a particular deity. A whole class of such seals bears psalms that conclude the short paean with the phrase "Have mercy!" It is also in the Kassite period that the Akkadian language started to become commonplace on seal inscriptions. In this same period some seals even took on the form of amulets intended solely to protect the bearer, enhanced in magical efficacy by the lustrous stones that the seal cutters used.

■ Introduction: The Movements of Cultures in Bronze Age Europe

Students of Neolithic and Bronze Age Europe are often overwhelmed by the preponderance of strange names given to the cultures that archaeologists have reconstructed as having inhabited the region. These cultures are typically named after the first site in which the culture was identified (called the type site), after a particular artifact that is distinctive of the group (usual pottery), or after a practice that is typical of the group (perhaps burial practices). Most of these groups were small chiefdoms, which could have had as few as 5,000 members or at the most up to about 20,000 members. These chiefdoms shared some general traits from region to region but were not homogenous, each having its own unique cultural features.

Archaeology in Europe has generally been conducted at a local or national level. Very few attempts at synthesis over Europe as a whole have been attempted. Each country uses its own terminology and own research agendas. There is an archaeological division between Eastern and

Western Europe that reflects not an ancient boundary but instead the boundary of the Cold War of the twentieth century, a time when archaeologists were unable to share information easily. Ancient boundaries are further confused by modern nationalism and ethnicity, since many of these modern identities are seen to be rooted in groups that existed over 4,000 years ago.

One of the key problems facing European archaeologists is how to understand the movements and connections of these disparate groups. Given that some regional attributes were shared among groups that maintained their own unique behaviors (preserved as artifacts), how can archaeologists differentiate one group from the next? It is very difficult, in the study of ancient European society, to understand what evidence constitutes evidence for trade, for migration, and for warfare, since all of these three types of activities can manifest the same types of archaeological remains. The evidence, for archaeologists, is preserved as different artifacts and practices

(manifest as collections of artifacts) gradually spreading and subsequently disappearing throughout Europe. The following entries describe some of the major patterns of material culture movement patterns throughout Europe.

—Kevin M. McGeough

The Corded Ware Phenomenon

Around 3000 BCE, a new material culture assemblage appeared in northwestern Europe. The most distinctive artifact associated with this new assemblage is the corded ware ceramic vessel. These types of pots are handleless drinking vessels (much like the beakers that appear in the same region later). The rims of the vessels flare out, a style called everted by ceramic specialists. The pottery is decorated with impressions left

by rope (or cord) wrapped around the vessels before they are fired, leaving distinct horizontal bands. This kind of decoration appears much earlier in the pottery of the eastern European steppes. The exact relationship between corded ware pottery and the pottery of the steppes is not clear.

Archaeologists are not entirely certain what these vessels would have contained, but the best guess is some kind of alcoholic beverage, most likely a type of mead made from honey or wine imported from the south. Archaeologists have taken these vessels as evidence of the spread of drinking culture from southern and eastern Europe. Another possibility is that these pots may have contained cannabis; there is strong evidence for the use of cannabis as a narcotic substance in eastern Europe at this time. Other possibilities include nonalcoholic beverages or honey.

Corded ware pottery appears alongside another distinct type of material culture, the shaft-hole ax. This is a type of ax that had existed in the region prior to the appearance of corded ware; with the appearance of corded ware, this kind of ax appears in much greater frequency. A shaft-hole ax is a stone ax that would have had a wooden handle. A hole for the shaft of the handle is carved into the stone. Both of these types of material culture (corded ware pottery and shaft-hole axes) are found associated with individual male burials. Other materials found in these burials include beads, flint tools, and bone tools. Usually the burial is located under a large human-made mound.

Andrew Sherratt and others argue that this change reflected a larger social change in which individual wealth became more important than communal wealth and monuments (such as Stonehenge). It is difficult to determine whether this new material culture was associated with the movement of a new population into the region or whether it represented the adoption of new types of lifeways by people already living in northern and western Europe. Settlement patterns associated with the corded ware phenomenon differ from previous patterns: houses are small, and there is no evidence for ceremonial or social centers. Corded ware burials are individual, whereas the burials associated with mega-

➤ WHAT IS AN ARCHAEOLOGICAL ASSEMBLAGE?

One of the most important concepts in archaeology is the idea of the assemblage. An assemblage is a group of types of material culture that are consistently found together and are assumed to reflect a specific culture. In the early years of the twentieth century, archaeologists (especially in Europe and North America) concentrated on identifying sets of material culture that appear again and again through a specific region. It was assumed that while one type of material culture found in isolation could represent any number of social phenomena (it could have been deposited in the region by trade, through conquest, as a souvenir, as an heirloom, etc.), if more than one type of artifact is consistently found together, then this reflects a particular lifeway. Many of these identifications by early archaeologists are still used as designations for particular groups; European archaeologists still talk about Corded Ware People, Bell Beaker People, etc. It is also important to distinguish between an assemblage and a sub-assemblage. A subassemblage refers to a set of material culture that is consistently found together and reflects a particular activity (as opposed to a particular culture). Thus, a hunter's assemblage may include a quiver, bow, and arrows, and a blacksmith's assemblage may include an anvil, a hammer, and some metal ingots.

—Kevin M. McGeough

lithic monuments are collective. Corded ware settlements coexist alongside settlements associated with henge and megalithic monuments for about 200 years. After this, megalithic settlements fall out of use, and the settlements associated with corded ware spread down into central Europe (Switzerland and Bohemia) and east along the coast of the Baltic Sea (all the way to Poland). This may reflect an early pan-European cultural group or may simply reflect material culture customs common to the northern half of Europe.

Beaker People

The Beaker People are named after a handleless ceramic cup or beaker that became widespread in central and western Europe during the Late Neolithic period and the Early Bronze Age (ca. 2800–1900 BCE). Beakers have a bell-shaped cross-section and are commonly referred to as Bell Beakers. These vessels are generally found in burial contexts with a combination of daggers, arrowheads, wristguards, and v-bored buttons, which indicates to Burgess and Shennan that there was a proliferation in the production of weapons and archery equipment by the Early Bronze Age. Beaker burials generally evoke male-oriented warrior symbolism and mark a breakdown in the prevailing social structure of temperate Europe, which sees the emergence of ranked societies. The changing social and economic conditions of the age are far-reaching, as is the distribution of Beaker artifacts, which are found from Ireland to Hungary and from Scotland to the Mediterranean.

Beaker culture "Glockenbecher" bell-shaped vase which gave its name to a period of the Late Neolithic or Chalcolithic (copper) period. From Laa an der Thaya, Lower Austria. (Erich Lessing/Art Resource, NY)

According to radiocarbon evidence, the earliest Beaker pottery was manufactured in the Rhine Delta by the mid-third millennium BCE. Beaker burials are found in Spain and Portugal shortly afterward, suggesting to Sherratt that distant marine contacts were established by the Late Neolithic. Traditional theories attribute the movement of Beaker artifacts to the migration and trade of a coherent Beaker culture. In reality, there is little evidence to suggest that a distinct cultural entity existed. The single burial tradition in flat graves and burial mounds, once considered a hallmark of the Beaker culture, is not consistent throughout Europe; beakers are found in chamber tombs in Brittany, in both communal barrows and cremation burials in Britain, and within settlements in Ireland but never in burials. Although few Beaker settlements are known, village and house plans vary considerably between regions. Beaker material culture thus represents a dispersed range of related artifacts as opposed to a monolithic assemblage that reflects uniform social and economic conditions across geographic regions.

► THE SOCIAL SIGNIFICANCE OF THE BEAKER

Beakers played important roles in drinking rituals and may have been used to consume alcohol or other stimulants. Although relatively pure alcoholic drinks were available in Egypt (beer), Mesopotamia (beer), and eventually the Classical Mediterranean world (wine), the required ingredients were not accessible in the necessary quantities to produce such material in temperate Europe during the Beaker period. Beakers probably contained a mixture of fermented materials, although there is little direct evidence to know for certain. One of the earliest examples of alcoholic beverages in Europe comes from a preserved birch bark container in a Bronze Age burial in Denmark that contained clover, honey, fruit, leaves, and cereal grains; it was an ale, a fruit wine, and mead. This type of drink was probably used in social settings during the Beaker period, possibly by elite who had access to such material or perhaps among travelers and newly established contacts.

—Noah V. Honch

The appearance and spread of Beaker artifacts is probably related to two major agricultural developments: the introduction of the plow and the increased exploitation of secondary animal products. Brodie argued that the efficiency of the ox- and later horse-drawn plow created agricultural surpluses that fostered population growth in ways that were not possible in previous periods. Secondary animal products, such as milk and wool, diversified agrarian produce and allowed humans to inhabit areas with soils of marginal fertility. Resulting settlement expansion led to increasing contact between communities, which became progressively important with the exploitation and trade of copper and copper ores. Metal weapons, tools, and archery gear became important symbols of a Beaker warrior ethos that previously did not exist. Some individuals were able to accumulate material wealth and prestige by controlling the flow of copper and other metals, presenting challenges to traditional social roles in ways that gave rise to early stratified societies.

Emergent social differentiation cannot itself explain the mechanisms by which Beaker mate-

rial culture spread through much of Europe. Although traditional explanations advocate population movements and cultural diffusion, it is difficult to evaluate their relative effects. Price et al. have argued that strontium isotope data from the teeth and bones of Beaker burials indicate that a significant proportion of local populations in central Europe are of nonlocal origin. Given the increasing importance of the horse and established marine travel, migrations could certainly account for the movement of material culture, particularly if local skirmishes over resources provided the motivation. It is problematic, however, to draw direct connections between material culture and ethnicity—to assume that Beaker pottery equals Beaker people—and to accept that a coherent body of artifacts was carried and traded by a distinct cultural group. It is equally difficult to assume that many or all indigenous communities in Europe were receptive to Beaker materials and chose to obtain them by trade alone. In Yorkshire, however, there is evidence that Beaker materials were incorporated into a developing prestige goods economy at a local level. Although the specific causes behind the movement of Beaker artifacts remain unclear, the distribution of material culture certainly points to widespread cultural influences and rapid sociocultural changes in central and western Europe during the Late Neolithic period and the Early Bronze Age.

Urnfield Culture

The Urnfield culture is characterized by the widespread appearance of cremation burials in central and eastern Europe during the Late Bronze Age. Traditional inhumations are largely replaced by incinerated human remains, which are typically placed in ceramic urns and buried under earthen barrows or long beds. Cremation burials are generally found in dense clusters, or urnfields, that show expansion with successive interments and symbolize long-term connections between small communities and the local landscape. Urnfield burials demonstrate a profound break with established burial practices and represent a substantial shift in the cosmological belief systems of many regions, including north-eastern France, the Carpathian Basin, northern Italy, and the northwest European Plain.

The Urnfield culture shows continuity with earlier Middle Bronze Age traditions but introduces significant cultural changes. During the Middle Bronze Age, the Tumulus culture buried multiple individuals in earthen mounds or barrows, which are usually isolated entities that contain distinct families. With the introduction of cremations, there is a shift toward single-burial barrows and the formation of clustered urnfields, which preserve the remains of a local community and suggest the development of a collective identity. The internal organization of urnfields probably reflects kin relations, but on a larger scale they serve as visible landmarks and possibly define the territories of neighboring groups.

The proliferation of urnfields is related to population movements and competition over land and prestige items. Upon the collapse of the Mycenaean civilization, there was a population influx of Mediterranean groups along the Middle

> POLITICAL AND SOCIOECONOMIC ASPECTS OF HOARD DEPOSITS

With technological advancements in bronze metal casting, swords and other metal artifacts became symbols of power and wealth. While massive hoards are found in rivers and other water bodies, they are virtually absent from early urnfields. The specific reasons for this are unknown, but the deposition of hoards almost certainly took place in a public context. The public arena was a good venue for local leaders to compete in the ceremonial destruction of material wealth, to convey their power, and to reaffirm their roles in the larger community. Hoard deposits also ensured the scarcity of bronze and kept its value high. This solidified the economic standing of those who controlled the bronze trade, which invariably included community leaders.

—Noah V. Honch

and Lower Danube. Early urnfields are primarily associated with farmsteads and primitive field systems but are increasingly found in marginal agricultural regions, suggesting population pressure and resulting competition over land encouraged further resettlement. Fortified sites are known in many regions and are particularly apparent in Poland and eastern Germany. In this context, urnfields probably legitimized the territorial claims of local communities by providing evidence of long-term settlement and ancestral inheritance.

Relationships between the living and the dead were reinforced by the intentional deposition of metal hoards, which also served political and socioeconomic functions. Although most early urnfield burials possess few grave goods or lack them altogether, metal hoards of armor, swords, weapons, and other bronze artifacts are commonly found in rivers and other water bodies. The hoards may be votive offerings to deities but could also strengthen the relationship between communities and their ancestors, especially since rivers are known to have been perceived as portals to the otherworld of the dead by later non-Classical groups in Europe. The initial absence of metal artifacts in urnfield burials may be due to the collective power of

Ceramic jars and sieves from the urnfield at Tannheim, Germany, Bronze Age. (Erich Lessing/Art Resource, NY)

local leaders, whose communal responsibilities did not translate into material wealth. By the end of the Late Bronze Age, however, metal weapons and armor are commonly present in urnfields, and some elaborate burials are known to contain four-wheeled wagons and horse bits. By this time, communal leaders appear to own or control sufficient metal resources to convey wealth and power outside of obligatory ritual duties.

At the close of the Late Bronze Age there is a lack of grave goods in cremation burials, and urnfields go out of use. The specific causes of decline are unknown but probably relate to ecological problems and shifting trade networks. Roymans has argued that extensive farming may have contributed to the erosion or acidification of soils, rendering formerly abundant regions unproductive. Remaining agricultural land was scarce and became a source of competition, as indicated by the increasing appearance of fortified settlements. It was difficult for urnfield communities to trade for metals and other commodities without agricultural surpluses. Furthermore, iron emerged as the dominant metal, which could not be controlled along the same

lines as tin and copper ores; iron ores were less scarce, but the associated metallurgical technologies were considerably different than bronze working. With the emergence of the Hallstatt culture and extensive salt extraction in Austria, trade networks significantly changed, leaving urnfield communities to adjust under difficult circumstances. Urnfields had gone out of use in central Europe by the end of the Late Bronze Age, around 700 BCE, lasting slightly longer in peripheral areas of the Lower Rhine, which experienced the same fate during the sixth century BCE.

Unetice Culture

The Unetice culture appears in central and eastern Europe during the Early Bronze Age and is generally characterized by whole-body inhumations in earthen barrows or tumuli. The culture is named after a series of burials in the vicinity of Prague and frequently appears as "Aunjetitz" in German and English publications, which, as Sherratt describes, indicates the appropriate pronunciation. Unetice burials are renowned for the

diversity and sheer quantity of metal artifacts, which exemplify impressive technological innovations in bronze metallurgy and demonstrate the importance of overt display and ostentation in burial contexts. The degree of ritual display generally exceeds contemporaneous Beaker burials and is almost certainly linked to the accessibility and control of copper and tin ores.

Unetice cemeteries are usually associated with settlements. For instance, most burials at Brezno, Czech Republic, are located within meters of longhouses. Unetice cemeteries also reflect a level of spatial organization that is generally not observed by contemporaneous groups in other regions. Inhumations are relatively dispersed in Beaker burial areas but are frequently found in compact groups at Unetice sites. Some Unetice burials are found in roughly linear arrangements with inhumations aligned in the same direction, as is the case at Tesetice-Vinohrady, Slovakia, and Dolni Berkovice, Czech Republic.

Unetice burials are particularly known for the elaborate display of gold and bronze artifacts, which convey prestige and reflect the status of the deceased. Warrior symbolism is particularly pervasive, and many graves contain a variety of bronze weapons including swords, daggers, halberds, and axes. Well-known warrior burials include the burial mounds of Leubingen and Helmsdorf in Germany and Lekki Mound in Poland. The Leubingen barrow is 8.5 meters in height and covers an internal pitched-timber chamber that contains metal weapons and gold jewelry. The interred male burials are associated with a cushion stone that could be used for metalworking, suggesting that such a trade was prestigious and perhaps limited to particular individuals or classes.

Although most Unetice burials contain single inhumations, many show evidence of secondary interments and indicate that burials were reopened to inter the newly deceased. Burial mounds were probably important physical manifestations of kin relations and served as physical markers of ancestral relationships. Chambered burial mounds require more resources and labor time to construct than flat graves and reflect the status of those interred. While some Unetice burials contain wooden chambers and show oc-

➤ UNETICE METALLURGICAL DEVELOPMENTS

Many Unetice artifacts reflect an astonishing degree of metallurgical innovation. During the Early Bronze Age, the production of bronze artifacts primarily depended on simple casting techniques and subsequent physical reworking such as hard-hammering. By the Late Bronze Age, however, with efficient metal extraction, a higher demand for metals, and emergent social differentiation, important metallurgical advances were present in Unetice artifacts. Swords possessed metal hilts that were physically cast onto the blade; during previous periods, hilts were fixed to the blade with relatively flimsy metal rivets. Unetice metallurgists knew how to enrich tin on the surface of bronze weapons, making them appear to be made of silver. Some rare finds suggest that some Unetice metallurgists were already familiar with iron.

—Noah V. Honch

casional evidence of wood coffins, others are utterly sparse and bodies are scattered in trash pits, which may hold the remains of slaves or defeated enemies, perhaps some of whom were used to build large barrow mounds.

By the Middle Bronze Age, metal artifacts were easier to cast because of developments in tin-bronze metallurgy, which could produce harder end products than with copper alone. Although copper ore sources were common in many regions of Europe, tin was rare. The Unetice culture developed in areas with access to tin ores, such as the Fichtelgebirge and the Erzgebirge Mountains of eastern Germany. In general terms, bronze production could be mediated by the extraction and trade of tin ores. The Unetice likely played a dominant role in these processes and strongly influenced the distribution of metal ores throughout much of central Europe. In this context, it is little surprise that Unetice burials are among the first to engage in the purposeful display of elaborate metal artifacts.

The Unetice culture was involved in long-distance trade networks that connected northern Europe with the Mediterranean. Wealthy burials belonging to the Wessex culture of southern England contain Baltic amber and a variety of

metal artifacts including daggers, which originated in Brittany and central Europe. Mycenaean burials also contain Baltic amber, which inevitably traveled through central Europe to arrive in the Mediterranean. The Unetice culture was almost certainly the unifying point of contact between these groups. Many Unetice burials in the Carpathian Basin contain elaborately decorated horse bits, which suggests that horses were already used for riding in eastern Europe. Horses significantly enhanced travel efficiency and were an important means of establishing and maintaining long-distance trade networks involving the Unetice culture.

■ Introduction: Avenues and Routes of Travel

There are a number of sources of information that archaeologists can use to reconstruct ancient travel routes. Textual records describe the routes that ancient people took to get from one place to another, often even providing the ancient names of the routes. Archaeological surveys can identify the remains of ancient roads. Using advanced remote-sensing techniques, both aerial and ground, archaeologists can identify patterns in the landscape that hint at these types of ancient connections.

Indirectly, archaeologists can identify ancient routes by studying the distribution of artifacts. If an Egyptian artifact is found in what is now Iran, it must have gotten there somehow. By comparing artifact distribution patterns with natural boundaries (and natural paths and access routes through those boundaries), archaeologists can reconstruct, roughly, where ancient routes may have been found. Likewise, settlements within a given region are often located along important trade routes. Rivers are the most common, since they can often provide stable transit routes from one city to the next. In

the Syria-Palestine Bronze Age, sites were located roughly one day's donkey ride away from one another, which allowed for safe overland transportation.

While individuals would have traveled for many reasons, the development of distinct routes was certainly rooted in economics. The desire to acquire exotic goods from distant lands would certainly have been an impetus. Related to this but on a larger scale, the need to gain access to resources that were not available locally would have been very important. The Egyptians, for example, suffered from a lack of local timber resources, so they traveled to the port city of Byblos to acquire the famed cedars of Lebanon. Tin, an essential component of bronze, was only available in a few isolated areas (such as England and Afghanistan), so travel to these far-off locales would have been essential for metallurgy. Trade networks developed that facilitated the transport of such goods without necessitating any one individual (or groups of individuals) from having to make a long-distance journey. Sites were linked together, and goods could pass

from one area to another without the originator of the good and the receiver of the good ever encountering each other (or even really of knowing of the other's existence). Aside from economics, diplomatic routes and routes connecting the distant areas of large empires were also established.

—Kevin M. McGeough

The Via Maris

The Via Maris (Latin for “Way of the Sea”) refers to the land route from Egypt along the northern coast of the Sinai Peninsula and along coastal Israel to the Esdraelon Valley. This was the main source of overland communication between ancient Egypt and the Levant and indirectly to northwestern Mesopotamia and Anatolia. The earliest reference to this coastal highway is found at the Temple of Amun at Karnak from the reign of Seti I (ca. 1300 BCE), where it is referred to as the Way of Horus. In Exodus 13:17 it is likely that the route avoided by the Israelites and referred to as the “way of the land of the Philistines” was the same as the Way of Horus.

Evidence for a coastal land route between Egypt and Canaan exists as far back as the Chalcolithic period (4300–3300 BCE) but certainly is strongly in evidence by the beginning of the Early Bronze Age (ca. 3300 BCE). *Serekhs*, a sort of royal signature inscribed on pots during the Early Dynastic period of Egypt, are found at numerous Early Bronze Age I (3300–3050 BCE) sites in southern and coastal Israel and along the northern Sinai coast. A stretch of the northern Sinai 124 miles (200 kilometers) long was surveyed, and 14 clusters of short-term encampments were located in the sand dunes. In some cases the pottery found at the sites was predominantly Egyptian and in some cases predominantly Levantine (specifically from the city of Arad). It is likely that the sites were created as way stations along the coast stemming from the trade in copper ore and bitumen coming from Sinai and the Dead Sea region. By the end of the Second Dynasty of Egypt, however, this trade with Egypt temporarily came to an end, and most of these campsites begin to disappear midway through the Early Bronze Age II. The Early Bronze Age III is a period of minimal contact be-

tween Egypt and the now urbanized centers of the Levant. The Early Bronze Age III ends (ca. 2300 BCE) with military campaigns by Egypt in Israel that were probably staged by this route.

The Middle Bronze Age IIA (ca. 2000–1750 BCE) sees a resettlement of the coastal Levant. However, the bulk of the trade between Egypt and the Levant was now conducted by sea between Egypt and the great trade center of Byblos on the coast of Syria. As a result, the Way of Horus was of less importance during this period. The Middle Bronze Age IIB/C (ca. 1750–1550 BCE) corresponds to a period in Egypt known as the Second Intermediate period. During this period, Egypt was ruled primarily by a group of foreign rulers referred to as the Hyksos. Recent archaeological investigations have made it clear that these foreign rulers originally came from the coastal Levant. As a result, the Via Maris would have regained some of its importance as a major communications route between Egypt and the homeland of the Hyksos. In the end, the Hyksos rule over Egypt ends with the expulsion by force of the Hyksos from Egypt by the pharaohs of the New Kingdom.

After the expulsion of the Hyksos, the Egyptians felt a need to expand their control over the eastern Mediterranean and began to make forays into southwestern Asia. In order to campaign in the region the Egyptians needed to have guaranteed control over the coastal land and sea routes into Canaan, and it is at this time that the Way of Horus becomes of greatest importance to the Egyptians. With Egyptian campaigns by Thutmose III and Amenhotep II against the cities of Canaan and the great kingdom of Mitanni came the establishment in Canaan of permanent military outposts along the Way of Horus. The relief at Karnak shows more than 20 way stations built by the Egyptians along the Sinai coast, and survey in the region has uncovered more than 40 such small sites as well as a major administrative center. Other administrative centers were built along the coast, with the main Egyptian stronghold at Gaza. Additional fortified centers were built farther inland to control access to the interior from the coastal road at key crossing points and passes. In addition to guaranteeing Egyptian lines of supply in the event of military action in the Levant, the Via Maris also controlled the

trade routes carrying wood, olive oil, wine, wheat, cattle, and slaves through the region.

The Red Sea

Today's Red Sea separates Africa from the Arabian Peninsula. At its north end, the Red Sea splits into two gulfs, the Gulf of Aqabah to the east of the Sinai Peninsula and the Gulf of Suez to the west. Traditionally, the Red Sea, or its various parts, has been equated with the Red Sea (*yam sup*) from the exodus story (Exod. 13:17–15:21, especially 13:8 and 15:4). The prophet Jeremiah probably identified *yam sup* (lit. "the Reed Sea") with the Gulf of Aqabah (Jer. 49:21),

Satellite view of the Red Sea, bordered by Africa and the Arabian Peninsula. (National Aeronautics and Space Administration)

► THE RED SEA AND THE SEED OF REEDS

The Hebrew name *yam sup* has been translated as "the Red Sea" since at least the third century BCE. The ancient Greek translations rendered *yam sup* as *erutha thalassa*, a name that could refer equally to the Red Sea or to the entire Indian Ocean. The Latin Vulgate then translated the Greek *erutha thalassa* as *Mare Rubrum*, from whence "Red Sea" later entered English translations. Ancient commentators as early as Jerome, Rashi, and ibn Ezra, however, suggested that *yam sup* properly meant "Sea of Reeds," based on Exodus 2:3 where *sup* means "reed" while *yom* is the general Hebrew word for "sea." Although *sup* may mean "reed," deriving from the Egyptian *twf* ("papyrus plant"), the relationship between *yam sup* and the literal meanings of the two individual words *yam* and *sup* remains problematic.

—Spencer L. Allen

while other biblical references suggest either the gulfs of Aqabah or Suez. Alternatively, other places mentioned in Exodus, including Pithom and Ramses (1:11) or Pi-Hahiroth, Migdol, and Baal-Zephon (14:2) suggest a location in the eastern Egyptian Delta. However, a precise location for any of these places is also difficult to determine. Although no consensus has been reached, most modern scholars accept that the biblical Red Sea was likely a reedy marsh in the eastern delta region. Thus, for geographic and literal translation purposes, scholars usually designate the biblical Red Sea as the Sea of Reeds.

The Bible provides multiple accounts of the crossing of the Sea of Reeds, including twice in Joshua (2:10 and 4:23). The oldest version is found in the Song of the Sea (Exod. 15:1–18) and the Song of Miriam (v. 21), the Bible's oldest examples of ancient Hebrew poetry. In this version, God piles the waters with his breath rather

than splitting them (vv. 8 and 10) and throws Pharaoh's forces into the sea (vv. 1, 4, and 21), where they sink like stone or lead (vv. 5 and 10). Thus, God leads the Israelites (v. 13), but no action is attributed to them.

The other account, Exodus 13:17-14:31, is actually two separate crossing stories that have been combined by an ancient Israelite editor. When separated, each of these versions still provides a full account of the crossing. However, each provides different, and at times conflicting, information about the crossing. The so-called P, or priestly, version (14:1-4, 8-9, 15-18, 21a, 21c, 22-23, 26, 27a, 28a, and 29) more resembles the famous scene from Cecil B. DeMille's 1956 epic *The Ten Commandments* than does the so-called J/E version (13:17-19, 21-22; 14:5-6, 10-14, 19-20, 21b, 24-25, 27b, 28b, and 30-31). Moses raises his arms in order to split the sea, allowing the Israelites to pass through, but when the Egyptians try to cross, the seawalls crash down upon them. Unlike the Song of the Sea, then, Moses and the Israelites are active participants in these events.

In contrast, the J/E account more resembles the Song of the Sea. The Israelites are passive, following Moses's orders to stand firm and be still while the cloud pillar separates them from the Egyptians. Instead of splitting the waters, J/E describes a wind that blows the waters back throughout the night. In the morning, Pharaoh's chariots pursue the Israelites but get weighed down in the muddy ground (v. 25) and attempt to flee. Notably, unlike P's account, the ground is not dry. When the waters return, the Egyptians are overtaken and wash up dead on the banks.

Emergence of Coastal Cities in the Northern Levant

By 4000 BCE, several significant cities had already begun to form in the Levant—the eastern Mediterranean coast—including Byblos, which became the first Phoenician city, and Ugarit 100 miles (165 kilometers) to the north, a leading Canaanite city.

Byblos emerged early as a major sea-trading power in the Mediterranean largely due to densely populated Egypt's demand for cedar from Lebanon. Egypt had almost no wood suitable for construction and sought the strong, fragrant cedar to build burial chambers and great temples, such as the one at Hierakonpolis in 3200 BCE. Archaeological excavations at Byblos show larger homes, public buildings, and massive city walls being raised in the years that followed the opening of that trade.

This good fortune allowed Byblos to expand southward along the coast of what is now Lebanon, founding the cities of Tyre and Sidon around 2750 BCE. Cedar and other trade goods from these three cities were tremendously in demand during Egypt's massive construction projects, which included the pyramids. The importance of the timber trade to Old Kingdom rulers is verified by archaeological evidence. For example, two boats made from cedar of Lebanon were found beside the Great Pyramid of Khufu buried for the pharaoh's use in the afterlife. When local supplies were not sufficient to meet the market demand, traders from Byblos, Sidon, and Tyre obtained more supplies from sources across Anatolia and the Aegean to meet Egypt's demand for materials. In antiquity the Aegean island of Santorini (also known as Caliste or Thera) was the one most frequently associated with these Levantine traders.

Beautiful purple cloth was created by the Phoenicians using dye from the murex shellfish. The resulting fabric was so highly treasured that it became a symbol of royalty. The Phoenicians made delicate glass bottles, which they filled with precious cosmetics and ointments obtained from exotic lands. Their intricately crafted bowls of gold and silver were highly prized, even being complimented by Homer in the *Iliad*. They were

BIKAI'S EXCAVATIONS AT TYRE

Cedar boat buried beside the Great Pyramid at Tyre. (Jon Bodsworth)

From 1973 to 1974, Patricia Bikai led an excavation team at Tyre in Lebanon that carefully worked its way down layer by layer to bedrock. In so doing, she confirmed the date given by Herodotus for the founding of this city in the third millennium BCE. After more than 700 years of occupation, serious depopulation of Tyre was observed around 2000 BCE. Then by 1425 BCE the city began to grow again, flourishing after 1200 BCE. Bikai dated each of the 28 layers by examining pottery fragments found in the soil and matching them to identical pottery from other cities where dates had already been well established. When combined with historical information such as that provided by Herodotus, archaeological work such as this has provided an excellent window into the past.

—Sanford Holst

also well known for selling colorful trinkets and costume jewelry to clients who could afford no better.

The development of bronze technology led to new economic possibilities for these people. Bronze is created when copper is mixed with tin, and these Levantine traders supplied those

raw materials in great volume. They kept the sources of their tin secret, but some assert that much of it came from the lands now known as France, Spain, and possibly Cornwall in England.

Some scholars posit that just before 2000 BCE, fierce Amorites began harassing Ugarit and Byblos. To escape these raiders, a partial migration of people took place from Tyre, Sidon, and Byblos. Current research suggests that they moved westward and may have participated in the rise of the Minoans at that time. Five hundred years later, the fall of the Minoans coincided with a return of large populations to Tyre, Sidon, and Byblos under difficult circumstances. Ugarit took advantage of its southern rival's problems and finally grew into a great city in its own right after 1500 BCE. At that same time, King Thutmose III of Egypt led his troops northward into the Levant and established tributary status over these lands east of the Mediterranean.

When the Hittites later marched southward from Anatolia (present-day Turkey) and took Ugarit, that city became a major port for the Hittite empire. This caused Tyre, Sidon, and Byblos to lose their long-held leading role in Mediterranean sea trade. Then, in the years just before and after 1200 BCE, the Sea Peoples devastated virtually every city from the Aegean Sea to Gaza near Egypt. For this reason, historians originally thought that the Phoenicians came into existence after 1200 BCE, since they were seen to be flourishing after that time. However, archaeological excavations have clearly established that there was no destruction at Tyre, Sidon, and other Phoenician cities at this time.

The Canaanite city of Ugarit was utterly destroyed by the Sea Peoples and was never rebuilt. The powerful Mycenaeans and Egyptians also fell into decline at this time. The Phoenicians took full advantage of this window of opportunity and spread trading outposts westward the full length of the Mediterranean Sea, recovering their position as major sea traders.

Among the remarkable papyrus scrolls found in Egypt is one written by an official named Wenamun, who went to Byblos to buy a cedar boat for his temple around 1075 BCE. This journal of his trip gave a firsthand look into this coastal city at that time. It also suggests how the much-

earlier cedar boat came to be buried beside the Great Pyramid and underscores the long-standing trading relationship between these two lands.

Sailing through the Gulf

By 2500 BCE, major changes occurred in the pattern of trade among Mesopotamia, the Iranian plateau, South Asia, and the regions now known as the Gulf States. Sumer ceased direct trading across the Iranian plateau, becoming instead a key player in the Persian Gulf, where it had long-standing trade links. Here it interacted with three countries: Dilmun, Magan, and Meluhha.

Earlier, the name “Dilmun” had been applied to the Arabian coast around Tarut, but during the third millennium it came increasingly to mean Bahrain. The island is blessed with sheltered harbors and sweet water and was a three-day sail from Sumer. Seagoing ships could put in at Dilmun to take on water and fresh supplies, including the island’s exceptionally fine dates. Agricultural land on the island is limited and probably became inadequate to support the burgeoning third-millennium population. In exchange for imported grain, Dilmunites could offer fish, mother-of-pearl, and “fish-eyes” (pearls). Increasingly, Dilmun also served as an entrepôt, exchanging Mesopotamian goods for materials imported from farther south. Its role in international trade is underlined by the presence of weights on two different standards, that of Mesopotamia and that of Meluhha. Large warehouses and the island’s distinctive Persian Gulf seals—round stamp seals bearing motifs such as two people drinking from a vessel through straws—attest to the importance of trade to Bahrain, supported by the frequent mention of Dilmun in

Sumerian texts as the source of many commodities that the island could not have produced.

These included copper, which in reality came from Magan, as did diorite. Like Dilmun, Magan probably shifted its geographical focus through time, including within its purview the Makran coast of Iran, but in the later third millennium it referred mainly to Oman. Substantial copper deposits on the Omani peninsula were mined by 2500 BCE. Maysar in the Wadi Samad has remains from various stages in processing copper ore. Pottery and other imported items found in burials and at Umm-an-Nar on the west coast attest to relations with traders from farther north, and on the east coast the fishing village of Ras al-Junayz traded with people from the Indus Valley who sought their copper and bitumen and perhaps materials imported from farther west along the Arabian coast.

To the Sumerians, these Indians’ homeland was known as Meluhha, the source of many essential and luxury goods—fine timbers, ivory, gold, agate and carnelian, and other exotica such as haia birds (peacocks)—although they may never have visited it themselves. The Indus town of Lothal in Gujarat, through which some of the trade was channeled, has yielded abundant evidence of warehouses, tradeable goods and materials, and Indus seals—square steatite stamp seals bearing a motif and a short inscription, alas as yet undeciphered (and probably undecipherable)—as well as a Persian Gulf seal. If foreign traders came here at all, it seems that they were from Dilmun.

The Meluhhans, however, certainly traveled to Dilmun and Sumer. Persian Gulf seals and cylinder seals have been found bearing Indus-style motifs and inscriptions in the Indus script but with unfamiliar sign sequences, suggesting non-Meluhhan words. A fine cylinder seal identified its bearer as a “Meluhha interpreter.” In the Ur III period, Lagash was said to have had a village of Meluhhans in its territory, presumably a trading colony. One of the Meluhhans’ most valuable exports was lapis lazuli, the former mainstay of trade across the Iranian plateau. They did not prize this material themselves, preferring harder stones that could take a high polish, but they went to the lengths of establishing a colony at Shortugai in Afghanistan to monopolize the

supply of lapis to West Asia. Shortugai may also have been used to control trade in other Afghan valuables, notably tin ore, which now reached Mesopotamia via the Gulf.

Sargon of Akkad boasted that ships of Meluhha docked at Akkad; Ur's quays also saw trading ships arriving from the south. Numerous Akkadian and Ur III texts record goods issued to and received from merchants engaged in the Gulf trade. But in 2004 BCE, Ur was sacked, and the highly bureaucratic Ur III empire gave way to smaller political units centered on individual city-states. Gone was the capital and financial security needed to fund large-scale ventures. Merchants continued to trade, but their ships were smaller (40 gur maximum, a marked contrast to the vast 300-gur ships of former times) and their voyages more restricted, going no farther than Dilmun, whose role as middleman now increased significantly.

Further changes were soon to come. From around 1800 BCE, the Indus civilization experienced the decline and eventual collapse of city life. Rural communities, and in some areas towns,

continued to flourish, but the era of international trading ventures was over. At much the same time, the political heart of Babylonia shifted northward to Babylon. Sumer ("Sealand") became a backwater, and for some centuries Mesopotamia ceased to be involved in Gulf trade.

■ Introduction: Modes of Transportation

Other than walking, there were three main modes of transportation during the period between 4000 and 1000 BCE: by boat, by horse, or by pack animal/draft animal. The use of these three modes of transportation was profoundly important. Humans could travel longer distances more readily, with greater speed and less exhaustion. They were not limited to what they could physically carry; thus, new trade and migration possibilities became available. Interregional connections were facilitated, since messages could be sent quickly and goods and ideas could be exchanged.

For long-distance travel, sea and river travel were by far the most important modes. Water allowed large (and heavy) amounts of goods to be easily transported. Watercraft were significantly faster than any overland modes of transportation. Sea and river travel were, however, limited

by the season; in certain times of the year (depending on the location) it would have been too dangerous to travel on water, or, as in the case of the Mediterranean Sea, seasonal winds and currents would have made transportation too difficult, given the available technology.

Horses were important in much of Asia during this age, allowing nomadic and seminomadic people to utilize vast expanses of territory in their subsistence regimes. The domestication of the horse also allowed chariots and cavalry to become important components of warfare. Draft animals, such as oxen, allowed people to travel overland with heavy loads. People could ride in or walk beside wheeled carts pulled by these strong animals over long distances. Donkeys could carry smaller loads on their backs or could carry a human passenger. In general, donkeys were more suitable for transportation over

smaller distances and were commonly used for day-to-day transportation within a community.

Wheeled transport was an incredibly important technological development that seems to have developed independently in the Near East and China. Without engines, wheeled transportation had to be pulled by a horse, a draft or pack animal, or a human. As wheeled transport became more sophisticated, land transportation became more feasible. This technology also led to innovations in military strategy (the chariot) and agricultural technology (the plow).

Seafaring and Navigation, 4000–1000 BCE

During the fourth to the first millennia BCE, seafaring significantly expanded its role in human history. Since earliest times, people had used sea transport for fishing and exploration. They also used seafaring to settle new lands. People had crossed wide expanses of water to populate islands in many parts of the world as early as 50,000 years ago. Ireland, Crete, Cyprus, Sri Lanka, Australia, Sumatra, New Guinea, Taiwan, Japan, and the Philippines are just a few of the places where emigrants crossed wide bodies of water to settle new lands. Then, with the emergence of the civilizations in the regions of the Nile, Tigris, Euphrates, and Indus rivers about 6,000 years ago, seafaring developed into a major commercial and political element of complex urban centers. Archaeological and other evidence provides a picture of ships of the time carrying people, materials, and goods overseas in the eastern Mediterranean and the western Indian Ocean. Sailing in the time period becomes a major ingredient in international trade, with sea transports carrying large amounts of goods to markets, natural resources to manufacturing sites, and military men and equipment to protect and extend commercial interests.

The significant role of maritime trade in the fourth to first millennia BCE is well exemplified by its participation in the bronze industry of the eastern Mediterranean. Large amounts of tin and copper, the essential alloys of bronze, were carried by sea throughout the region during this period. A cargo of metal ingots in one vessel un-

covered by nautical archaeologists, for example, measured more than 11 tons. Furthermore, tin was imported by sea to the island of Cyprus, a major center of the manufacture of bronze objects, from as far away as Great Britain. The bronze tools, weapons, and other objects made on the island were then distributed by sea transport to sites in the Aegean, the Levant, and Egypt. This extensive commercial activity soon attracted piracy and sea marauders. To protect the maritime commerce, military leaders began to carry troops and supplies in ships to guard the sea routes, repulse pirates and marauders, and also expand their spheres of influence both on the sea and on the shore. Control of the sea and naval battles became a part of political and military history.

Commercial and trading interests of the earliest civilizations had recognized that ships were the cheapest, safest, and fastest means of transporting goods over large distances. Furthermore, seagoing peoples had developed the technology for constructing vessels with large carrying capacities and the ability to navigate them successfully over the open sea. While the evidence for the extent and impact of seafaring during the three millennia considered here is incomplete, the historical records, pictographs, and traditional archaeological research have provided us with an overall picture of the times. Furthermore, there has been a significant increase in our knowledge during the last 50 years due to ethnographic research among seagoing peoples and new developments in archaeology. From the ethnographic research, we have learned how it was possible for ancient mariners to navigate over open seas without modern instruments. At the same time, new discoveries around the world have provided us with a more detailed picture of the materials transported, the life of sailors, and the character of the vessels used in the early maritime trade. In particular, the introduction of nautical archaeology has made possible the close examination of ancient shipwrecks never before accessible to investigators. These additional sources have provided us with a greater appreciation of the role that early seafaring played in human history.

One of the technological advances that enabled the transportation of large amounts of

> ULU BURUN

Copper plano-convex or 'bun' ingot with incised marks perhaps denoting ownership. This particular mark may represent a ship's quarter rudder. (Institute of Nautical Archaeology)

The Ulu Burun shipwreck is one of the most important finds in Bronze Age archaeology because it is a snapshot of the Mediterranean Bronze Age trade network. In the 1970s archaeologists found the remains of a ship lying on the sea floor off the coast of present-day Turkey near the village of Ulu Burun. The ship sank with all of its cargo more than 3,000 years ago (ca. 1320 BCE according to dates obtained from tree rings). At the time it sank it was carrying mostly raw materials, especially large ingots of tin and Cypriot copper. The ship also carried raw glass, ebony wood, containers of foodstuffs and spices, and quantities of Mycenaean pottery. The mixed nature of the materials on board, some coming from Egypt, the Levant, Cyprus, and the Aegean, makes it almost impossible to pinpoint where this ship originated or who was manning it. It is therefore a superb demonstration of the international flavor of Late Bronze Age society.

—Susan Helft

material was the construction of plank boats. While it was possible to carry tons of cargo on large log rafts (they were used for seafaring along the South American coast in more recent times), the number of vessels involved and the large tonnage of materials transported were better served by planked boats. The planks were cut from logs and then sewn together to make the shell of the ship. Mortise and tendon joints were also used to prevent the separation of the planks, and the hull was caulked to ensure its seaworthiness. No metal fasteners of any sort were used. These techniques enabled shipbuilders to construct vessels that extended the length, width, and freeboard of vessels far beyond that of any previous vessels. Sewn-plank boat construction continued to be used for carrying tons of cargo over long sea voyages until recent times. Large cargo vessels with this style of construction were still carrying cargo between India and Africa during the last century.

The international sea trade saw another technological advance in the use of sail power. Although sails were in use earlier, during the fourth to first millennia the standing rigging, control lines, anchoring devices, sails, and steering mechanisms on seafaring vessels saw numerous developments. Various styles of rigging were devised, many of which are still used today. Lateen, brailed square sails, and a form of Marconi rigging (with bendy, adjustable mast) enabled mariners to control a vessel without difficulty under normal conditions and adjust the sails when weather deteriorated. Combined with knowledge of the seasonal winds, rapid long-term voyages could be undertaken with increased certainty of survival. Furthermore, a vessel could easily travel 24 hours a day with a limited amount of crew.

Long-distance seafaring requires a number of basic elements. One is seaworthy vessels, and it has become clear that these were in use 6,000 years ago from the material evidence recently uncovered by nautical archaeologists. Long-distance seafaring also requires navigational techniques that ensure traveling out of sight of land and arriving in a timely fashion at a destination. The ability to secure sufficient food and water for the sailors during an extended voyage is also required. While there is some direct evidence of these capabilities provided by historical docu-

ments, most of what is known today is derived from ethnographic accounts of contemporary seafaring peoples. Seafarers have used birds for thousands of years to locate land; this was one of the navigation devices widely utilized. Early seafarers developed at least a portion of the knowledge known today among navigators in Oceania of sea animals, astronomical events, currents, winds, clouds, and bioluminescence that have enabled Polynesians, for example, to travel for hundreds of miles out of sight of land to find an island no larger than several city blocks. There is no doubt that long before the invention of the quadrant, the compass, and the clock, ancient seafarers had developed the ability to successfully navigate in open water. They also had fermented fruit, fruit pastes, dried shellfish, coconuts, and fire hearths aboard their ships that enabled them to travel for long distances without replenishing food and water.

Ships, Boats, and Watercraft

The first boats appear well before the first states, probably around 10,000 BCE. In the third millennium BCE, however, water transportation became increasingly more important as Egyptian

➤ THE PERILS OF EXPERIMENTAL ARCHAEOLOGY—THE OMAN BOAT PROJECT

On September 7, 2005, an international experiment that attempted to replicate ancient sea transportation methods began and ended. A team of scholars had reconstructed a reed boat covered in bitumen, replicating the types of boats thought to have been used by sailors from ancient Oman. The eight-person crew had prepared for a long and difficult journey from Oman to India, replicating a travel route thought to have been used by ancient mariners. A few hours after setting off the ship sprung a leak, and the sailors had to be rescued by the modern boat carrying the rest of the team. The project was subsequently canceled.

—Kevin M. McGeough

and Mesopotamian civilization developed. Mesopotamia depended heavily on irrigation agriculture, and thus numerous artificial canals were built from the Tigris and Euphrates throughout the countryside. The Egyptians utilized the overflowing of the Nile’s banks in order to irrigate their crops; controlling this flooding also demanded the construction of artificial canals. Since most Egyptian settlements were situated along the Nile River, river travel made sense. Thus, in both areas sophisticated ship-construction techniques developed by as early as 3500 BCE. These early craft would have been towed by individuals walking on either side of the narrow canals, rowed by oarsmen on the boat, or punted using large poles to propel the boat through the marshes.

The earliest evidence for Egyptian ships comes from artistic motifs found on Predynastic tomb walls (Hierakonpolis) and on ceramic vases. These vessels are not depicted in much detail, but some general observations can be made. The ships were sickle-shaped and may have had masts. The ships seem to have numerous oars projecting out from the hull, but no rowers are apparent. None of the images are depicted to scale since the figures standing on board dwarf the vessels.

At the Egyptian cemetery of Tarkhan, planks from an ancient ship were recovered. Since

these planks have survived, it is possible to make some observations on early ship construction. The planks were sewn together but also made use of mortise and tenon joints. Mortises are rectangular holes drilled into the sides of the planks; a tenon is a peg inserted into these holes to bind planks. The combination of these two building techniques kept the vessels watertight. These vessels were alternate ended, meaning that either end could function as the prow or stern. This was necessary since the narrow canals on which these ships floated would not allow the vessel to turn fully around.

The remains of actual Egyptian ships have been recovered from funerary complexes. Believing that death involved a ship voyage through the afterlife and that anything buried with the deceased could be used in the next world, some kings were buried with ships. One of the most important early ship burials is located at the site of Abydos, associated with the grave of the Early Dynastic king, Den. Den's ship was over 50 feet (15.2 meters) long and constructed in a manner similar to that found at Tarkhan.

A significantly larger vessel has been recovered from the complex of the Great Pyramid at Giza. Two boats were discovered; one was left in the sand, and one is on display in a small building next to the pyramid. These were King Khufu's boats and, like his pyramid, were quite large, over 150 feet (45.7 meters) long. Made of cedar imported from Lebanon, these were the most expensive types of ships available in Egypt at the time. Even given the size and cost, they were still constructed of mortise and tenon planks lashed together.

Ships from ancient Thera may also have been built according to Egyptian standards. Miniature frescoes found on the walls of the West House in Akrotiri, which was destroyed by a volcanic explosion, depict Minoan ships. These ships were probably double-ended like Egyptian vessels; both masts and oars are depicted on the ships as well. This is different from later Greek vessels, which have one elongated end that projects outward and were primarily powered by rowing.

Outside of Egypt, there was more diversity in ship construction. In Oman, reeds were lashed together and covered with bitumen. These ves-

sels could have had sails or oars. Cuneiform texts from Mesopotamia discuss the boats of Meluhha, Dilmun, and Magan (and use the place name for the ships from those regions). The Mesopotamians believed that these vessels differed significantly. Canaanite ships were well suited for transporting cargo with a small crew. They had rounded hulls and traveled very slowly. A merchant ship flotilla from Canaan is depicted on the walls of the tomb of Qenamun in Egypt. The Ulu Burun shipwreck, excavated off of the coast of Turkey, was this type of vessel.

Horses

Horses were among the last animals domesticated in the Old World. As such, they were more specialized in their use than most other domesticated species. Until the late Iron Age, for the most part horses were used only in warfare or by the nobility. Even in warfare their role was limited by lack of the stirrup, which made riding them in battle difficult. Therefore, horses were most commonly used to draw war chariots.

The domesticated horse (*Equus caballus*) was first tamed somewhere in Russia or Ukraine about 4000 BCE by the forebears of the people who today speak Indo-European languages. Some of these horse-using groups migrated south and east and came into contact with the urban cultures of the ancient Near East. Some groups were assimilated into the Hurrian groups living

Hittite archer on a chariot with charioteer, Anatolia, ninth century BCE. (Gianni Dagli Orti/Corbis)

in Anatolia, where they formed the empire of Mitanni. Other Hurrian groups also played an important role in the Hittite empire and spread their culture southward into the Levant. With them they brought the use of horses as carried by a group of elite chariot-using warriors called the *maryannu*, a Mitannian term meaning “prince or noble.” The earliest attested horse-training manual comes from the Hittite capital at Boghazkoy and is written in Hurrian.

The introduction of chariotry to the military technologies of the region made possible the first empires. During the New Kingdom, Egypt dominated the Levant as a result of their chariotry. In Anatolia, the Hittites become a major force in the region thanks in part to this technology.

Horses first arrived in Mesopotamia around the end of the third millennium. They are mentioned as *ANSHE-KUR-RA* or “asses from foreign countries.” In the Mari letters, *sisu* horses are also mentioned for the first time. In the Mesopotamian world, the Assyrian empire arose largely as a result of its massive chariot force. Chariotry provided the shock and awe of their day by adding a mobility and surprise factor that heretofore had been lacking. The Harappan or Indus Valley civilization may have come to an untimely end

as a result of invasion by Indo-European horse-riding nomads around 1500 BCE. The wide use of horses as beasts for burden and as riding animals would await developments in the Iron Age and the increased availability of horses to average people.

Donkeys

Donkeys (*Equus asinus*) played an important role in the economies of the ancient Near East. The wild forebear of the donkey was the wild ass (*Equus africanus*), native to both Africa and West Asia. It was likely domesticated independently in both regions. The first domesticated donkeys are thought to have appeared around 4000 BCE, with the oldest remains found so far at the site of Tell Rubeideh in Iraq, dating to the Uruk period levels at that site. Early evidence has also been found in Egypt in the form of third-millennium BCE donkey burials. Evidence for their early domestication in Mesopotamia can also be seen in the earliest cuneiform writing, which includes a sign for the word *ANŠE* (donkey) consisting of the stylized view of a donkey’s head.

Donkeys and wild asses were well adapted to life in desert climates. They handle heat well, do not need much water to survive, and are happy living off of desert scrub. This, in addition

► THE DONKEY—A FORM OF TRAVEL STILL USED TODAY

Thanks to the adaptability of the donkey in harsh climates, its calm nature, and its ability to haul a great deal of weight, donkeys are still commonly used today throughout the world as beasts of burden. Unlike horses that are often high-strung and expensive and require a great deal of care in poorer locales, donkeys make for an inexpensive alternative to tractors, cars, and trucks. In modern Turkey, for instance, it is still common to see donkey carts carrying produce to market.

—David R. Lipovitch

to their ability to haul great weight, made them ideal animals for crossing the distances between Egypt and the Levant and Nubia and between North and South Mesopotamia and Syria. The domestication of the donkey made long-distance trade between these various groups much easier and allowed the spread of new technology and innovation in a manner that took place at a much slower rate before their domestication. In addition to their use in donkey caravans, they were often used as an everyday beast of burden, hauling plows or carts or carrying loads for farmers. They only begin to be gradually replaced by horses in Mesopotamia during the Kassite period (1602–1595 BCE). They were also used for short-distance travel as riding animals. Their physique, however, made them uncomfortable for longer journeys or for riding at high speed.

Before the introduction of the horse, donkeys were crossbred in Mesopotamia with onagers (a form of wild ass) to produce mules. The high-spirited onagers loaned a temperament to these mules that was prized for use in hauling early chariots. Thanks to both historical documentation and archaeology, we know of Egyptian convoys of donkeys at the end of the Old Kingdom traveling as far south as the Fifth Cataract. Earlier donkey caravans between Egypt and the Levant of the Chalcolithic (4300–3300 BCE) and Early Bronze Ages (3300–2000 BCE) may be at least partially behind the development of complex cultures in that region. The tomb paintings at Beni Hasan from the Middle Kingdom (ca. 1900 BCE) show Semitic traders visiting Egypt

and carrying their wares and equipment on donkeys. Evidence in the form of donkey remains in the Levant show their presence as early as the Chalcolithic period at Teleilat Ghassul (ca. 3000 BCE).

In Bronze Age Mesopotamia, donkeys made possible the trade colonies and networks that existed between Anatolia and Assyria for trading Anatolian tin and Mesopotamian textiles. They also played a key role in the growth of major trade centers such as the Bronze Age Mari in Syria, where caravans of 3,000 donkeys are recorded. In Second Intermediate period Egypt (1650–1550 BCE), the presence of donkey burials is a sure sign of the presence of the Hyksos, foreign rulers of Egypt originally from the Levant. During the Late Bronze Age (ca. 1550–1200 BCE), the Amurru (the biblical Amorites) were renowned in Mesopotamia for their donkey breeding. Their prize donkeys were used only by the wealthiest farmers and caravaners.

Wheeled Transportation

Without a doubt, the wheel was invented long before 4000 BCE. Yet the first wheel recovered intact from an archaeological site dates to about 3500 BCE and comes from ancient Sumer.

Wheeled vehicles appear in early cuneiform writing (at this stage still pictographs). These vehicles (if they can be taken as such) were simply wooden planks set atop wheels. By 3000 BCE wheeled vehicles in Sumer were more complex. Artistic depictions of battles feature four-wheeled carts pulled by what may be donkey (or possibly oxen). A similar device emerged in Europe around 3000 BCE. Whether it was based on the Sumerian wagon or a separate European innovation is unclear. The earliest depiction of a wheeled wagon may actually be European. The wheels of these vehicles were massive, cut from a single piece of wood (from trees that would have to have been more than 400 years old). Wagons were buried with warriors in parts of eastern Europe, and some have been fully recovered by archaeologists. Model carts found in the Indus Valley, dating to as early as 2600 BCE, attest to the use of the wagon in that region as well, there pulled by oxen.

In Egypt, wheels were less useful for transportation given the sand and marshes that were typical of the region. Travel on the Nile River was much more efficient (and to some extent still is today). Yet given the Egyptian propensity for constructing monumental architecture consisting of heavy pieces, something was necessary to drag these components across the desert landscape. The solution to this was the sledge. A sledge looked much like a gigantic sleigh. The sledge would be guided onto rollers (usually wooden logs) and could be dragged over the logs. The logs would roll and facilitate the movement of the sledge (and its heavy load). Logs that had already been rolled over would be removed from behind the sledge and resituated in front, allowing the sledge to be pulled with a finite amount of rollers.

The development of the spoked wheel allowed for the construction of the first chariots, primarily intended for combat or display. Drawn by horses, chariots could move substantially faster than wheeled wagons. In combat, the

➤ THE FIRST IMAGE OF THE WHEELED WAGON

In 1976 archaeological excavations at the Neolithic site of Bronocice in Poland uncovered what may be the first image of a wheeled wagon. Incised on what has come to be called the Bronocice Pot were images of what may be five wagons. Each image appears to be a slightly skewed form of a bird's-eye view, although the perspective is quite skewed (if the images are wagons). At the outer edge of each corner of a rectangle is a circle, perhaps a wheel. A circle rests in the middle of the rectangle, perhaps a human or a ceramic vase. A triangular shape extends out of the front of the rectangular shape, terminating in a long single line. Perhaps this was where an ox would have been yoked. Other imagery on the pot depicts a tree, a river, and perhaps roads. Dated from 3635–3370 BCE, if these are wagons then they are the earliest depictions.

—Kevin M. McGeough

chariot functioned as a mobile firing platform, allowing an archer to move over the field. It was also used in parades of kings and higher officials, especially in Egypt. The chariot appeared throughout Asia, from Anatolia to China, and in Africa, Egypt, and eastern Europe.

■ Introduction: Thinking about Foreign Lands

As the first states emerged, new conceptions of thinking about the self and others also emerged. Groups were no longer construed solely along familial or tribal lines. Many people came to see themselves as part of a larger ethnic group or polity. Egyptians saw themselves as Egyptians and as distinctly different from other groups that inhabited the Near East. Nubians, for example, could come and live and work in Egypt, but they were not Egyptians. Likewise, Egyptians could move to Syria, but they remained Egyptians. An important part of this development of group self-understanding was the identification of who was not part of the group. This process, which scholars call “othering,” most often involved an explicit discussion of the differences of people conceived as foreign (as opposed to explicit attempts to define what makes members of the group belong). Othering was part of a long-term discourse, as conceptions of who was and was not part of the group changed over time. In studying this ancient discourse of otherness, scholars keep in mind that many of the statements about so-called foreigners in ancient texts and artwork inform more about the group that created the account rather than the group about whom the account was created.

The greater contact among different groups in this period mixed with the more sophisticated means of expression available (most importantly the development of writing) led to new types of descriptions of the “other.” Artists depicted people from other lands using stock imagery that reflected the realities of foreign dress and appearance but marked them as distinctly different from the local population. The first travel stories were written and allowed non-travelers to experience the cultures of distant locales without ever venturing away from their own community. Stories that do not explicitly involve travel were often set in far-off locales, providing insight about regions away from home. Military narratives were numerically the most common types of accounts of foreign lands. More often than not, foreigners were depicted as faceless, dangerous hordes that were valiantly dispatched by the royal army.

—Kevin M. McGeough

The Tale of Sinuhe

The Tale of Sinuhe ranks as one of the most important and well-documented pieces of literature from ancient Egypt. Surviving versions of the text include 5 papyrus copies from the Middle Kingdom and Eighteenth Dynasty and some 30 shorter excerpts from later in the New Kingdom. The latter group consists primarily of schoolboys’ copies inscribed on potsherds or limestone fragments (both of which are known as ostraca), which were copied as part of the scribal training curriculum. The tale is an acknowledged masterpiece of classical Egyptian verse and abounds with high-flown diction and deliberately crafted grandiloquent narrative.

The story is presented in the form of an idealized funerary autobiography. Early researchers tended to interpret it as being based upon, or even directly copied from, the autobiography of an actual official who lived at the beginning of the Middle Kingdom. However, virtually all research in more recent decades has been unanimous in recognizing Sinuhe’s tale as a self-consciously literary composition that merely uses the autobiographical form as a framing device for the central theme of travel abroad. Despite its fictitious character, the Tale of Sinuhe provides a useful window into Egyptian perceptions of their neighbors, which was informed by their own cultural interaction, trade, and military presence in foreign lands from the Sinai to Byblos.

The basic plot can be summarized as follows. An Egyptian official of modest rank named Sinuhe (“Son of the Sycamore”) is returning from a military excursion near the Egyptian-Libyan border under the command of the crown prince, Senwosret. News reaches them that the king, Amenemhat I, has died. For reasons that are left deliberately ambiguous, Sinuhe becomes gripped with terror at the thought of possible revolt breaking out at the capital, and he flees abroad. Passing from Egypt across the Sinai, Sinuhe’s flight eventually brings him to Retjenu (Syria-Palestine) and the forests of Qedem, a major Lebanese cedar-producing area, east of Byblos. From there, a local chieftain named Amuneshi meets

Ostrakon of *The Tale of Sinuhe*. Probably from Thebes, Egypt, Nineteenth Dynasty, around 1250 BCE. (British Museum/Art Resource, NY)

the wayward Egyptian and is impressed by his stories of Egypt's prosperity and the high praise given to its new king, Senwosret I. As a result, Amuneshi invites Sinuhe into his tribe, elevating him above even the chief's own children. Amuneshi then offers his eldest daughter to Sinuhe as a bride and grants him dominion over a veritable land of milk and honey called Yaa, which he governs with great success, conquering neighboring countries and tribes and siring children of his own. The turning point of the story comes with a duel between Sinuhe and "the strongman of Retjenu . . . a hero without equal," who hoped to seize Sinuhe's considerable landholdings for himself. This episode has often been compared with the much later biblical tale of David's combat with Goliath. Like David, Sinuhe slays the hulking brute and seizes his possessions, thereby growing in fame and importance. Following his victory, Sinuhe is again overcome with emotion, but this time it is a profound longing for Egypt that grips him, in contrast with his earlier desire to flee. A correspondence with King Senwosret ensues in which Sinuhe is assured of his safety if he should return. Sinuhe then leaves his Asiatic family and landholdings and returns to Egypt to throw himself on the king's mercy. When Sinuhe reaches the royal court, the king heaps praise upon him, restores him to his former status, and makes provisions for Sinuhe's proper Egyptian burial, even granting him the highly unusual privilege of a pyramid tomb in the royal necropolis.

—Joshua Roberson

➤ SINUHE'S MORALITY

To the modern reader, Sinuhe appears to be a rather unsympathetic hero. He is egocentric, he exhibits cowardice as a deserter, and he abandons his family when they fail to satisfy his spiritual malaise. The point of the story for the ancient Egyptians, however, would have been much different from our own. Perhaps the most important moral, from the Egyptian perspective, is that life abroad may seem enticing and adventurous, but even great success achieved in a foreign land is a pale reflection of modest happiness in Egypt, a proper burial, and the blessings of the king.

—Joshua Roberson

➤ CONVENTIONS OF "OTHER" IN EGYPTIAN ART

Foreigners were frequently depicted in Egyptian art. Often, foreigners were used to artistically indicate chaos incarnate. Hence, the king is often visualized in Egyptian art slaying foreigners. Related to this, foreigners were portrayed on the sole of the royal sandal, the tiles of the palace, footstools, and other places the king was wont to tread, causing the king to regularly trample over his foreign enemies and thus continually defeat chaos. During some eras, it was common to depict foreigners as being bound not by cords but instead by the two heraldic plants of Egypt, demonstrating that conquering others was a necessary part of unifying Egypt.

Foreigners were featured in other roles in Egyptian art, most notably in the exchange of goods. In contrast to Egyptian clothing, which did not hold dye well, foreigners were often depicted in flamboyantly colorful outfits. Egypt's immediate neighbors were each portrayed in a consistent manner in Egyptian art. The Nubian was typically shown with black skin, tightly woven hair, and jewelry. The Libyan was usually depicted with lighter skin, pointed beard, a penis sheath, and a feather. The Semite was shown with lighter skin and fuller beards. For each group Egypt regularly encountered, an artistic convention developed that allowed the artist to unmistakably convey to his audience the ethnicity of his subject.

Patriarchal Travel Narratives

In the Bible, the patriarchs were the male heads of Israelite families or clans. The earliest patriarchs were key and prominent figures in the history of ancient Israel, and their stories are found today in the book of Genesis, the first book of the Bible. The triumvirate of progenitors of early Israelite religion were Abraham, the first father of the ancient Israelites (Gen. 12–24); Isaac, his son, (Gen. 25–36); and Jacob, his grandson (Gen. 25–36). It is their stories that set up the larger narrative of the Hebrew Bible (Old Testament).

Today, the historicity of these patriarchs is largely contested due to the absence of direct archaeological evidence for their existence and a number of anachronisms found in the textual record (e.g., the attestation of Abraham's camels in Genesis 12:16, which were not domesticated until the second millennium), but many scholars agree that the literary depiction of the patriarchs' travels, lifestyle, economics, and social background found throughout Genesis largely support the historical milieu of the second-millennium Near East. No other period in ancient Near Eastern history, for example, supports the widespread travel of nonroyal persons throughout the Fertile Crescent.

Regardless of their historicity, the literary stories of the patriarchs, or what are more commonly referred to as literary cycles, with their origins based in early orality, only preserved later in time with the final written form of the book of Genesis, depict all of the nuances of a peripatetic lifestyle: land, water, and travel are the essential means of survival in the Middle East. The cycles are framed by genealogies that figure so prominently in the book of Genesis.

These genealogies are important for historians and archaeologists for reconstructing birth rights, land tenure and claims, pedigree, and the prestige of Israelite tradition. Family life was also an important concern in Genesis, and religion was practiced through the construction of altars and stone pillars at numinous sites. Commerce, politics, religious custom, and long-distance intertribal marriages form the conflicts of the oral stories and were at the root of the wide scope of travel for the patriarchs.

Abra(ha)m, the earliest patriarch and the father of Israelite religion, was originally from "Ur of the Chaldees" (Gen. 11:10–32). This location is the archaeological site of Tell el-Muqayyar, the famous city of Ur in Babylonia. The Genesis account records that Terah, the father of Abram, took Abram along with his brother Nahor and nephew Lot and moved them northwest of Ur to the city of Haran on the Balikh River. From there, Abram and Sarah, his wife, traveled southwest through Syria into Canaan to Shechem, Bethel, and the Negev. Although he dwelt in southern Canaan for most of his days, specifically the area of Hebron, he journeyed into Egypt twice during times of famine (Gen. 12 and 20) in the so-called wife-sister motifs, where he introduced his wife as his sister to the pharaoh of the day. Abram engaged in military skirmishes with local tribes (Gen. 14), participated in an eternal covenant with a patriarchal deity who changed Abram's name to Abraham (Gen. 17), and promised to him plentiful progeny, land, and a perpetual name (Gen. 12:2–3). Abraham begat a son with his wife's servant, Hagar (Gen. 16), engaged in a rite of circumcision (Gen. 17:27), and finally received his promised hereditary heir, Isaac, at the extraordinary age of 100 years (Gen. 21).

The cycle takes a sudden turn of events in Genesis 22 as Abraham is asked to sacrifice this firstborn and beloved son, Isaac, on Mount Moriah, but the binding of Isaac is overturned as Abraham's proven faith in the midst of his test of devotion demands God's interference: an animal is provided to serve as the replacement for a human sacrifice, and so the narrative serves as an etiology for the institution of animal sacrifice at the Israelite temple in Jerusalem. Abraham's place in the biblical tradition is preserved at the end of the cycle by the fulfillment of the eternal prom-

➤ WHEN DID THE BIBLICAL PATRIARCHS LIVE?

The exact date of the patriarchal periods within the scope of the second millennium is difficult to ascertain, and scholars vary between the Middle Bronze Age (2000–1500 BCE) and the Late Bronze Age (1500–1200 BCE), each one on the basis of the textual attestations to the various nomadic groups of the ancient Near East such as the Amorites, Hurrians, and Arameans. The excavation of key archaeological sites such as Ebla, Mari, and Nuzi along with the discovery of extensive cuneiform library archives in the palaces of these cities have aided in the historical reconstruction of the social background of the world of the patriarchs. For most scholars, then, the textual and archaeological evidences point to the Middle Bronze Age as the most plausible period of time for the travels of Abraham, Isaac, and Jacob. Cuneiform archives from Mari on the upper Euphrates refer to the Amorites, a group of seminomads, moving counterclockwise around the Fertile Crescent. And archaeological excavations at Beni Hasan in middle Egypt have uncovered wall paintings of seminomads entering Egypt from Canaan as part of the ancient donkey caravan routes. Furthermore, the patriarchs are frequently depicted in the book of Genesis as dwelling in tents next to large

Ruins of Ebla in present-day Syria. (James Gordon)

city-gates; architectural features are also attested in the archaeological record of the Middle Bronze period. Thus, the patriarchs were nomadic pastoralists by definition. They lived in tents, moved herds with the various seasons of the year, and eventually were well respected and wealthy in the geographical area of Canaan.

—William Zimmerle

ises of the covenant: he now has progeny, holds land, and has accumulated great wealth. He is interred in the burial plot that he has acquired from the Hittites at Hebron, and his death in Genesis 25 marks the end of a great patriarch but the beginning of a famed name and father of a multitude of Israelites, a fact that is retold many times throughout the entire biblical canon.

Isaac, the son of Abraham and Sarah, is second of the three patriarchs and is depicted in his Genesis cycles as naively innocent in comparison to his father, Abraham, and his son, Jacob. Like Abraham, Isaac traveled to Egypt because of the famine (Gen. 26) and repeated the mistakes of his father in a third wife-sister motif. He also returned to Mesopotamia, the land of his ancestors, in the pursuit of a long-distance marriage with Rebekah (Gen. 25). Although comparisons with the Abrahamic cycles reveal a sparsity of data available for Isaac's life, most of Isaac's

stories indeed center on the Negev Desert, specifically the area of Beer-Sheva.

Jacob, the final patriarch of the three, was probably a northerner, and his cycles place him in the region of northern Canaan, specifically Shechem and Bethel as well as northern Transjordan (Mahanaïm and Penueïl). Forced to flee Transjordan because of fraternal strife with his brother Esau (Gen. 27), Jacob went to Haran to visit his uncle Laban. Along the route, Jacob encountered the theophany of God at Bethel (Gen. 28), eventually married both Laban's daughters Leah and Rachel in Haran, and served Laban as a slave for 14 years before departing from Haran. During Jacob's return to Canaan, he encountered God again at Penueïl and, like his grandfather Abraham, received a name change from Jacob to Israel (Gen. 32). Eventually he reconciled his relationship with his brother Esau (Gen. 33), fathered the 12 sons of Israel, and

returned to Egypt to find his long-lost son Joseph in the final chapters of Genesis. Jacob, too, was buried in the field of the cave of Machpelah at Hebron, as recounted in Genesis 49–50, which serves as a reminder, along with the burial of the other two great patriarchs and their wives, of the covenant promises made between the Israelites' forefather Abraham and the God of their fathers.

Mesopotamian Diplomacy

Foreign lands were often a source of desirable materials, which could be obtained either by diplomacy and trading or by aggression. Both strategies were variously employed by Mesopotamian states, depending on the nature of the players with whom they had to deal. Other lands could also be the source of aggression, whether raids by tribal groups or full-blown invasions by hostile states, or they might become allies against the aggression of third parties.

Traders and ambassadors played a key role in articulating international relations. The economic and political importance of their activities made it expedient for rulers to protect messengers and merchants traveling through their domains; where the local leader, whether settled king or tribal sheikh, could not maintain law and order, travelers were at risk from highwaymen or hostile natives. A messenger might therefore be a military man, furnished with a fast horse by the first millennium, and accompanied by an armed escort. The Neo-Assyrian kings built royal highways with way stations to expedite the movement of couriers throughout their lands. Rulers often issued their messengers a passport valid for a particular mission: this pre-

vented local red tape impeding his journey, although it did not guarantee safe passage beyond the messenger's own state. However, a reciprocal arrangement developed between states that wished to engage in diplomatic activity, the envoy being furnished with an escort by the state to whom he was sent; failure to supply such an escort was a strongly hostile sign.

Particular events might encourage an exchange of messengers, for instance expressing good wishes for a monarch's recovery from ill health or congratulations on a victory. Envoys (*mar shipri*) bore written messages, although they were often illiterate themselves. A senior envoy, a relative or close confidante of the king, might also be empowered to conduct oral negotiations. Although envoys were often treated well and generously entertained, they were at the mercy of the ruler to whom they were sent and could be visited with the displeasure or hostility he felt toward their masters or held as hostages.

Good relations were promoted and maintained by the exchange of gifts and by treaties negotiated orally or by letter and ratified by solemn oaths, whose breaking would call down devastating divine retribution. Their terms might include a commitment not to aid each other's enemies, agreements to repatriate runaways, and arrangements to support and protect merchants. Despite superficially good relations underwritten by treaties, there were often undercurrents of suspicion or friction between states, and diplomats were expected to keep their eyes and ears open as spies for their own ruler. Although treaties were often sealed by royal marriages, hostages might also be taken to encourage the honoring of commitments. Fugitive princes from overthrown regimes might also be kept as political pawns, to be used as a threat to keep the current monarch in line or installed as a puppet ruler. Failure to return such rival claimants to the throne, on the other hand, was a hostile gesture and could be a source of prolonged friction.

Politics and Statecraft

For the ancient Egyptians, the Egyptian state was not merely a political entity in the manner in which states are conceived in the present. Egypt was a living entity that required careful maintenance and sustenance, like any organic body requires. Egypt was an inseparable unit, consisting of the land, its people, the animals and plant life, the deities, and anything else that fell within what were thought to be the natural borders. The king (called pharaoh in the New Kingdom) was the chief caretaker of this land. Thought to be of divine descent, the king protected the state from the forces of chaos that threatened the land. Ancient Egyptian literature uses numerous metaphors to describe the king's relationships to his subjects. He is most often described in paternal terms, the chief father of Egypt. Other times, his subjects are referred to as wives of the king. The Egyptians measured the years in reference to the reigns of their kings; thus, cosmology and statecraft were inextricably interwoven. Yet the king's powers were limited, although they may not seem to have been to those who constructed the pyramids designed as tombs for the kings. The concept of *maat*, often translated as "balance," provided a conceptual guideline for the enacting of statecraft, helping to limit gross misconduct and limitless absolutist behavior.

Ancient Egyptian statecraft was unusual in this era in its relatively consistent precepts and its long duration. However, some of the tendencies of statecraft were typical of the first states, which emerged in Mesopotamia (and its periphery) and in China. These first states were organized somewhat similarly, although one needs to be careful to not ascribe too much cross-cultural similarity. Even the act of translating ancient words for statecraft can bring unjustified assumptions. For example, during this period the term "king" implies (incorrectly) a conceptual similarity between ancient rulers and the kings who ruled in Europe and elsewhere in later times. Still, these ancient states were typically ruled by a sole individual, whose authority was derived from a number of possible avenues: divine inspiration, achievements in warfare, or dynastic succession, to list a few possibilities. Yet given the technological constraints of this era, these early states were fairly decentralized. Even when power was centered on an absolutist ruler, it was beyond the political capacities of this absolutist ruler to fully centralize authority.

The king (called pharaoh in the New Kingdom) was the chief caretaker of this land. Thought to be of divine descent, the king protected the state from the forces of chaos that threatened the land.

The formal state was not the only type of polity that developed during this time. By the term “polity,” archaeologists mean the largest autonomous political unit of a given culture. For example, the state of ancient Egypt was an extensive polity ruled by a king but divided into a number of smaller political organizations, called *nomes* (which are best translated as “administrative divisions” or “provinces”). Each nome was governed by a *nomarch* who was answerable, at least in theory and often in reality, to the king. Outside of Egypt, many polities in this period had tribal or familial authority as the highest unit of governance. In these types of polities, everyone in the community knew one another, although actual practices of governance varied considerably. Between these two extremes were city-states and chiefdoms. City-states were polities where authority was centered in the political leadership of a city and extended into that city’s hinterland. Chiefdoms operated on a similar scale but were less bound to an urban center.

For many societies, ancient political structures can be reconstructed through ancient textual evidence, left as a remnant of government activities. For societies that lacked writing (or lacked a writing system that can be translated by modern scholars), this enterprise can be far more difficult. Instead, archaeologists are forced to rely on identifying particular material markers or indicators of government and, by comparing these indicators with better-understood societies, reconstruct governance by analogy. Certain types of monuments and architecture are typical of certain types of governance. Stonehenge, for example, which is found in a rural area away from a major city, is the type of monument that is typical of a chiefdom-level society since it required centralized planning to construct but is located away from any signs of centralized state authority. Likewise, a site with very little difference in the sizes and quality of houses and minimal evidence for public or state architecture likely reflects a less-stratified governance than that found in a state. Population size is one of the best indicators for archaeologists. For example, state-type governance would have been unwieldy for the smaller population groups typical of North America at this time.

Still, archaeological indicators are not always accurate and must always be treated with suspicion. The civilization of the Indus Valley is one culture that seems to defy easy explanation regarding its political organization. The population size and other material culture traits (such as complex infrastructure and writing found in administrative contexts) are indicative of an early state. However, archaeologists are not satisfied that any public architecture relating to governance can be identified in the remains, let alone any typical indications of centralized leadership.

—Kevin M. McGeough

■ Introduction: City-States and Chiefdoms

During this age, city-state- and chiefdom-style political organization arose in a variety of areas throughout the world. These were small-scale polities, usually with populations numbering between 5,000 and 20,000 people. They were internally organized according to rank. Often this rank was tied in to lineage, family groups that claim one common ancestor. Rank could be relatively fluid in these societies, often based on prestige of the family lineage, which could wax and wane. This organization differs from state-level societies where social stratification is connected to class and becomes much more entrenched. Leadership in these societies tended to be hereditary once leadership was entrenched in a particular lineage. The origins of this leadership are more variable. In some cases, leaders come to power because of military prowess and exploits or because of the accumulation of large amounts of wealth. Other times, especially in the case of city-states, a lineage is installed in a leadership position by a stronger external polity. This was the case with the city-states of Syria-Palestine in the Late Bronze Age, where minor kings were established in cities by foreign Hittite and Egyptian overlords. Other powerful officials within the community gained their power through their relationship to the leader. Generally, the closer an individual's relationship to the leader, the more powerful that individual was.

Although city-state and chiefdom types of government are relatively similar, there are some key differences. The most important difference is the role of geography. A city-state is a government that is fixed in a permanent urban location. This city is the center of authority and power within the polity. Typically there is a hinterland that extends beyond the city (essential for provisioning the urban center with food produced through agriculture), and sometimes smaller villages fall within the city's sphere of influence. The real basis for a city-state's power lies in its economic power, most commonly when a city is a major node along an important trade network. Since the city has the ability to command the flow of resources along this trade network and

at the same time has enough locally produced food for its own needs, it may have quite significant regional power.

Chiefdoms usually have permanent settlements, but political authority is not intrinsically tied to economic geography in the same way as with a city-state. The authority of the leader is based more on lineage (and the concomitant prestige of that lineage) than to the governance of a particular city. Chiefdoms usually have a wide variety of economic specialists within the community, like city-states, but the movement and exchange of resources is not as centralized. Chiefdoms of this period do typically have centralized religious or ritual centers, however. The ruler's power is usually associated with the ritual center. Thus, the basis for the leader's authority, on the surface, seems more based on symbolic and religious power.

—Kevin M. McGeough

Authority in Stateless Societies

Not all ancient civilizations knew the institution of statehood. The ancient Indus civilization (ca. 2600–ca. 1800 BCE) and the Danube civilization (ca. 5500–ca. 3500 BCE) were not organized as states but as socioeconomic commonwealths (or oecumenes) where lively trade relations sustained relationships of mutual advantage. Statehood was also absent from the formative period of ancient Chinese civilization, that is, the late Shang dynasty (thirteenth to eleventh centuries BCE), and only gradually developed during the reign of the Western Zhou (eleventh century–771 BCE).

Authority in societies without the organization of a state as their overarching structure does not manifest itself as an instrument of political control as in statehood. Rather, it is anchored in a pool of responsibilities to sustain the community, to safeguard a conflict-free interaction among its members, and to keep up a spiritual balance within the confines of a mythopoetic worldview. The self-supporting functions of state institutions such as bureaucracy and taxation (as revenue for the leadership) have no equivalent

in stateless societies where authority is delegated according to natural abilities of knowledge construction and the fulfilling of communal responsibilities.

In stateless societies, assigned natural authority may lie with a shaman or a person with the authority of a functionary to supervise communal ceremonies and to perform rituals intended to enhance sustainability and social harmony. The authority of such functionaries could easily extend to the organization of collective labor projects for the benefit of the community. In ancient China of the Shang era, shamans—mostly female—were privileged and influential as the keepers of precious knowledge, and this knowledge was identified as the teachings of the ancestors that were handed down from one generation to the next.

The authority of female diviners in ancient China is no exceptional phenomenon when viewing divination in a comparative perspective of cultures in Asia. Female shamans had a prominent status among Siberian peoples. The privileged role of female diviners in society has been preserved, for instance, in Korean society up to the present. Korean women diviners are called *mudang* or *mansin* (ten thousand spirits).

Chiefdoms in Mauritania

From about 2000 BCE to about 800 BCE, a chiefdom civilization appeared in the southwestern Sahara in Tichitt-Oualata (present-day Mauritania). This complex civilization arose in a time of climatic deterioration in which arable land and

good pasturage space were limited. Human over-exploitation (especially related to the overgrazing of herd animals) may have had an impact on the increasing aridity of the region. Rainfall would have been minimal in ancient times; cultivation would have to have occurred in the silt beds associated with seasonal lakes. Aquatic animals were exploited only in the earliest stages of this society; scholars assume that drought conditions forced the people of this region to look elsewhere for food resources. In this difficult environment, people subsisted on the cultivation of domesticated plants (especially millet), wild cereals, and pastoralist practices. Some evidence for the use of cereals is derived from the impressions of plants on the ceramics found at the sites, which allows scholars to identify the particular species of plants that were in use. Cattle, sheep, and goats are the best attested in the archaeological record.

The two best-known sites of this civilization are Dhar Tichitt and Dhar Oualata. These two sites are located about 186 miles (300 kilometers) from one another. Between them smaller villages have been identified, roughly every 3.1

miles (5 kilometers). It is likely that these smaller villages were subject to the authority of the larger villages, although exact boundaries are difficult to identify as is the center (or centers) of authority given the current evidence. Munson has argued that initially some of these villages may have been autonomous, but as arable land became scarce the smaller villages were incorporated into the political structure of the larger villages. An alternative explanation may be that as arable land became scarce, people were forced to settle in more marginal areas farther from the political centers but within manageable proximity to the homes of their families and civic or religious leaders.

Buildings at these sites are constructed of small stones usually arranged as circular compounds. Noteworthy are what appear to be the foundations for granaries and stone-walled coral areas. It is difficult to judge if these structures were in use contemporaneously with one another, and in fact there is considerable scholarly debate on the interpretation of evidence from Dhar Tichitt and similar sites. Some scholars such as Munson have argued that farming, although in use from early on at Dhar Tichitt, was in fact not important until near the end of the site's occupation. Holl has argued that what may appear to be differences in subsistence practices at the site do not reflect long-term change but instead reflect seasonal changes. In other words, at some times of the year farming was most important, and at other times of the year wild grains or pastoralism may have played a more important role.

There are few prestige items that have been recovered from Dhar Tichitt, and what has been recovered is consistent with prestige items found in other parts of the Sahara dating to this period. Beads made of precious stones seem to have been cherished, as were polished bracelets. Polished stone axes have also been found at sites.

> DHAR TICHITT

Dhar Tichitt is a group of villages in the southwestern Sahara Desert, in Mauritania. Situated on a cliff escarpment, this is an important area for understanding the origins of agriculture in Africa and for the study of complex civilization in Africa. Surrounded by hundreds of Late Stone Age villages, the main village of Dhar Tichitt is about 29.6 acres (12 hectares) in size; its northern side features a stone wall 6.6 feet (2 meters) high. The village itself consists of about 200 stone compounds, with alleys and roads twisting between the structures and larger plazas as public areas. Archaeological remains of animal bones and impressions of plants found on ancient ceramics have allowed scholars to reconstruct the subsistence economy of ancient Mauritania.

Canaan in the Middle Bronze Age

Early in the second millennium BCE, urbanism once again took hold throughout much of the southern Levant. A hierarchical relationship in the size of settlements indicates that large urban centers served as the seat of political power for what may be loosely described as city-states, though there is disagreement with regard to the degree of political complexity reached during the Middle Bronze Age. What would ultimately evolve into one of the great urban cultures of the second millennium BCE had its roots in the tribal societies of the preceding Intermediate

► FORTIFICATIONS AS STATEMENTS OF POWER

The massive earthworks that surrounded many Middle Bronze Age cities also point toward the existence of centralized power structures. They represent a significant investment of resources, above all, labor. The construction of the ramparts at Shiloh required an estimated 250,000 work-days—that is, it would have taken some 3,000 laborers roughly five years to complete the project—and the earthworks at Tel Dan would have taken an estimated 1,000 workers some three years. In a number of cases, such as Dan and Yavne-Yam, small populations relative to the size of the ramparts suggest that much of the labor force responsible for their construction was drawn from beyond the city itself. Those overseeing these projects would also have had access to the expertise of specialists (for example, designers and architects) as well as various other resources, including draft animals and building materials. The function of these massive rampart systems, however, is not always clear. Traditionally, it has been held that the earthen ramparts served as fortification systems, yet recent scholarship has challenged this view. For instance, what armies and types of attack were these structures built to defend against (for example, battering rams)? And would they have been successful against a siege? Numerous other questions have been raised. At Ashqelon, the earthen ramparts were capped by walls, yet it is not clear whether this system was intended to defend against surface attacks or

against tunneling meant to penetrate the city surreptitiously. Some of these ramparts were actually built prior to urban development within them.

Other explanations tend to emphasize the symbolic aspects of these structures. In the central hill country, ramparts formed small citadels, or “highland strongholds,” that served primarily as political centers, hosting large public buildings, temples, and storage facilities. In some cases, such as Ashqelon and Dan, elaborate gates were built into the ramparts, serving, on the one hand, as prestige architecture, and, on the other, as an effective way to monitor the movement of goods and people in and out of the city.

Regardless of their specific function, these massive constructions would have stood as highly visible symbols of power. Surely, there were rivalries between neighboring city-states as they vied for grazing and farmland as well as for access to trade networks. Monumental architecture served to enhance the status of local leaders and the cities in general while fostering a strong sense of identity based on location (for example, hailing from a certain city). The ruling political bodies of the city-states thereby engaged in “competitive emulation” or “one-upmanship.” Visible from afar, these imposing fortresses and lofty citadels could have facilitated the extension of political power from the cities out into the surrounding regions.

—Jonathan Golden

Bronze Age and early Middle Bronze Age. For instance, many of the large earthworks that surrounded the later Canaanite cities were actually established prior to urban development, serving, perhaps initially, as enclosures for the tents and semipermanent structures used by seminomadic tribal groups.

Information about political organization in the early Middle Bronze Age is also offered by Egyptian texts. The Tale of Sinuhe refers to pastoral groups with an internal sociopolitical structure, sometimes including several tribal leaders. The most important source of textual information for this period comes from the Twelfth Dy-

nasty Egyptian inscriptions known collectively as the Execration Texts. This series of curses on foreign places and peoples considered enemies of Egypt in effect creates the equivalent of a rough geopolitical map for Middle Bronze Age Canaan. More important, the texts all date from the mid-twentieth and mid-nineteenth centuries BCE, thereby providing a before-and-after picture for the process of urbanization. The earlier texts, on one hand, tell of tribes, sometimes with multiple leaders, and a landscape dotted with but a few cities (for example, Ashqelon and Jerusalem). The later group, on the other hand, lists the names of numerous cities, including Acre,

Hazor, Jerusalem, Laish, Qadesh, and Shechem, conveying a sense of widespread urbanization.

By the later Middle Bronze Age, the Canaanite countryside was divided up into a series of territorial units, probably distinct city-states or resembling kingdoms. Evidence from archaeological surveys reflects an eight-tier settlement hierarchy system (a system where the relative power of sites is recognized according to their relative size) by the later Middle Bronze Age. Hazor and Avaris (Tel el-Daba) alone may be classified as first-order gateway cities, and both are entirely unique cases. Hazor, which reached some 80 hectares, was more akin to Syrian cities of northern Canaan, while Avaris was a Canaanite city established in northern Egypt. Ashqelon (60 hectares; a hectare is equivalent to roughly 2.5 acres), Yavne-Yam (65 ha), and Kabri (35–40 ha), all located in coastal areas or along central routes, are considered second-order gateway cities. Third-order gateway settlements, such as Tel Dan (16 ha) and Tel Dor (10 ha), also situated along land and sea routes, were smaller, though perhaps equally wealthy. The inland valleys were dominated by regional centers such as Megiddo (more than 20 ha, including the upper and lower cities), Acco, Beth Shean, Kabri, Shimron, and Shechem. Primary centers of the coastal plain and Shephelah also included Tel el-Ajjul, Aphek, Gezer, Lachish, and Tel es-Safi. Survey data from this period also indicate a rise in the number of rural settlements, suggesting that there were a few relatively large centers surrounded by numerous small villages and farmsteads.

By the middle of the Middle Bronze Age, Canaan was divided into distinct political units subsuming urban, rural, and nonsedentary populations. These polities ranged from large chiefdoms to some of the region's first true city-states. Jericho, for example, was a small, autonomous community organized according to family and kinship structures, led, perhaps, by a council of clan heads. Shechem had broad influence in the hill country, which also played host to several autonomous polities of moderate size. Several vast city-states with large urban centers emerged. Hazor, all but abandoned during the Intermediate Bronze Age, saw rapid growth, developing into a bustling urban center that was the core of the consummate Canaanite city-state.

In Syrian texts from this time, Hazor is often mentioned as a contemporary of other kingdoms such as Carchemish, Ugarit, Babylon, Eshnuna, Qatna, Yamhad, and Kaptara (Cyprus or Crete). Reference is also made to emissaries from Babylon who took up long-term residence at Hazor, suggesting that there may have been formal standing political ties between the various city-states. Owing to its status and location, Hazor occupied a unique position as mediator between the Canaanite kingdoms and those of Syria-Cilicia. In many ways, Hazor was more similar to city-states of the Syria-Mesopotamian world system than to the rest of the southern Levant, and it was exceptional with regard to political organization. Avaris (Tel el-Daba) may have played a similar role as Hazor's southern counterpart, mediating between Canaanite city-states and Egypt. In both cases, political development in Middle Bronze Age Canaan must be understood in the context of a land situated between two developed states.

The Canaanite city-states no doubt had kings, but it is not until the end of the Middle Bronze Age, when local Canaanite/Amorite texts first appear, that it becomes possible for historians and archaeologists to speak of specific rulers. Textual sources show that kingship in Syria was passed down along descent lines, and mortuary evidence from the southern Levant suggests that descent groups were recognized and that status was hereditary; it is unclear, though, how this figured into the structure of political power. A number of cylinder seals and at least one scarab with the name of Hyksos rulers (for example, Aa-user-re) discovered at Tel el-Ajjul point to political ties between Egypt and southern Canaan. "Warrior burials" may represent the graves of individuals who served some royal court or guard.

In the absence of direct evidence for specific kings and political institutions, archaeologists may infer from the wealth of evidence for monumental architecture that some political body was able to command the contacts and resources necessary for sponsoring extensive public projects. Such projects are seen throughout Canaan. Palaces and "governors' residences" have been excavated at sites such as Tel el-Ajjul, Kabri, Hazor, Lachish, Megiddo, and Aphek. At the latter site, two governors, Takuhlinu and Haya, are

mentioned by name in cuneiform tablets dated to about 1230 BCE. These massive buildings, some larger than 1,000 square meters (nearly 11,000 sq. ft.), were elaborate in design, with broad, pillared halls, multiple storage rooms, and large courtyards. At both Megiddo and Shechem, the palace was located in the vicinity of the temple, though it is not clear that there was a direct connection. A northern influence is observable in a number of Canaanite palaces, particularly at Tel el-Ajjul and Lachish, which incorporated massive sandstone slabs, or orthostats, reminiscent of those in Syrian palaces. It would appear, therefore, that Canaanite kingship was modeled at least in part on the political structures of Syrian city-states.

Late Bronze Age Canaan— Under Egyptian Suzerainty

Much of Canaan was under the direct political control of the New Kingdom pharaohs during the Late Bronze Age. Owing to the great interest that the land of Canaan held for the kings of Egypt and Syria, there is a relatively large body of texts from both regions, in addition to some local inscriptions, that complement the archaeological evidence. The thirteenth century BCE, in particular, is illuminated by the extensive correspondence between rulers from Syria-Palestine and the Egyptian King Amenhotep IV, c. 1350 BCE.

Some of the key Egyptian texts yielding information about political organization during Late Bronze Age Canaan are the "Poetical Stele" of Thutmose III, the "Papyrus Anastasi I," the "Onomasticon of Amenemope," and a series of long topographical lists drawn up by the scribes of Thutmose III. Though some scholars have argued that references to Canaan are not explicit and are thus unreliable, others have countered that Canaan was clearly recognized as both a land and a people, which is precisely why this term is taken for granted in these ancient texts. Canaan was divided into independent political entities of various sizes, as indicated by both textual and archaeological evidence. Regional surveys indicate that there was less integration in the Late Bronze Age than during the Middle Bronze Age in most parts of Canaan (for example, Jezreel), with perhaps the exception of the central hill country.

Following the Egyptian king Ahmose's efforts to force the Asiatics out from their seat of power in the Delta, several subsequent pharaohs expanded the scope of the offensive, pursuing the Hyksos deep into southern Canaan in repeated campaigns. This is especially true of Thutmose III, who in year twenty-two of his reign (mid-fifteenth century BCE) launched the first of several attacks on Canaanite cities, including

Gezer, Megiddo, and Taanach, as recorded in inscriptions from Karnak. The Canaanite kingdoms of the Middle Bronze Age had always operated independently of one another, but when confronted with the threat of Thutmose III's armies, the Canaanite and southern Syrian kingdoms formed a coalition under the leadership of the king of Kadesh, with the support of Mitanni. Megiddo apparently served as the headquarters for this "league of Canaanite rulers." Defeat came nonetheless, and Thutmose III established rule over the region, extending the Egyptian sphere of control to as far north as the Orontes.

Much of this information comes from Egyptian sources, and the historical reality of these accounts has been legitimately questioned. Examination of these texts suggests that Egyptian stories about their struggle against a hated foreign power could contain some element of hyperbole. As for the archaeological evidence, destruction levels at southern and inland sites dating to the late seventeenth and early sixteenth centuries BCE seem to support the general historicity of certain events, though the pattern of destruction cannot be so neatly defined. The political upheaval experienced toward the end of the Middle Bronze Age was probably a long, drawn-out process, and some of the problems leading to the Middle Bronze Age collapse were well under way irrespective of Egyptian aggression, a factor that only hastened the process. Convalescence for the Canaanite cities following these events came slowly or not at all. There was a notable decrease in the number and size of Late Bronze Age settlements. Though a number of cities retained their urban character, they seem to have had less control of the hinterlands, where nomadic peoples were once again on the rise.

At the end of the Eighteenth Dynasty, Egyptian hegemony over Canaan appeared to be slipping, but with the transition to the Nineteenth Dynasty, further devastation was visited upon the region. Ramses I and his co-regent, Seti I, set out to reestablish dominance and even to outdo their predecessors, launching a series of campaigns into the region in the early thirteenth century that reached into Syria to the very margins of Hittite territory. Ramses II, whose influence in Canaan is demonstrated by the discovery

at Tel Dan (Area Y) of a scarab bearing his name, further extended control over Canaan, seeking also to contain the rapidly growing Hittite city-states to the north. Peace between Egypt and Hatti was not yet meant to be, and a great battle was fought between the two near Qadesh on the Orontes early in the thirteenth century BCE.

Certain titles used in both Egyptian and Babylonian texts suggest that Egyptians bore ranks and designations in administrations associated with Canaan. A letter from Alashiya, probably Cyprus, indicates Canaan as a "province" of greater Egypt, though some scholars have objected to the specific use of this term. Several sources, including later biblical texts, allude to specific borders delimiting Canaan and its cities. There are also references to Canaanite city kings, suggesting that the region comprised city-states with local rulers under the governance of the Egyptian New Kingdom empire. The Amarna Letters coming from Byblos, Beirut, and Tyre also allude to monarchs.

The pervasive Egyptian presence makes it difficult to distinguish between local, Canaanite political structures and those imposed by Egypt. For much of the Late Bronze Age, Egypt maintained a network of centers and garrisons in order to facilitate its domination in parts of Canaan that were under Egyptian control. It is also unclear whether the Egyptian presence was limited to government and administrative entities, or Egyptian civilians actually settled in Canaan. Political power was played out on an increasingly international stage. A mud-brick fortress dating to the Late Bronze Age has been found at Tel Sera (Str. X), where the material culture included Canaanite and Egyptian as well as Mycenaean and Cypriote goods. This trend is also reflected in the artistic styles of the day. A new form of hybrid iconography known as the "International Style," which combined elements from multiple cultural traditions, emerged during this period. Luxury goods of the hybrid style circulated within a broad supraregional system of interaction, becoming part of a royal vocabulary to which the kings of the day subscribed.

The existence of Late Bronze Age kings and regents is evident in the royal architecture from the period. Egyptian-style residencies, or

“governors’ residences,” have been unearthed at several sites, including Beth Shean, which functioned as an important administrative center and garrison in the Egyptian colony. Elaborate buildings interpreted as palaces have also been found at a number of sites apparently not under Egyptian control, indicating that local rulers enjoyed a certain degree of wealth and power. Whereas during the Middle Bronze Age the temple and palace at Shechem were built as part of one large complex, by the Late Bronze Age the two were distinct and the palace was relocated closer to the city gate. It is possible that this represents a split, perhaps even a rivalry, between the religious and political institutions. The same trend can be seen at Megiddo of the fourteenth century BCE, which has some of the most impressive examples of monumental architecture from the Late Bronze Age. Similarities between the overall plan of the thirteenth- and twelfth-century BCE palace at Megiddo and a contemporary palace at Ugarit have been observed, and, as a general rule, kings of southern Canaan continued to look northward for inspiration in royal architecture and iconography.

Northern Levant Coastal City-State System

A city-state system evolved in the Levant—the eastern Mediterranean coast—by 3200 BCE at Byblos, in the land known today as Lebanon. Public buildings, temples, parkland, and massive city walls, which show the result of community decisions, are evidence of the ways in which these people conducted their affairs. These civic activities seem to have grown out of the high-risk nature of sea trade, from which their great wealth developed. In sea trade, the loss of a single ship could devastate all who had invested goods and labor into the ship itself and the rich cargo it carried. As a result, the community appears to have spread the risks and rewards broadly among its members. In any event, it led to the development of councils at Byblos as well as at its daughter cities of Tyre and Sidon.

Councils remained strong despite the presence of kings. In fact, the importance of councils was an identifying mark of these cities—which would be later known as Phoenician—and of the colonies they founded. These included Carthage, where Aristotle commented on the role of the council—and of direct votes of the people—in governing the city. In all these cities, the council seemed to have a role in the selection of the new king, leading to that title being passed among the prominent families.

The cities of Byblos, Sidon, and Tyre maintained a political relationship, the leadership role of which was passed among the three cities from time to time. During their period of leadership, the king at one of those cities was regarded as senior to the others and served in a leadership role in times of duress.

► THE BAALAT GEBAL TEMPLE IN BYBLOS

Ancient public works in the city of Byblos are still visible today thanks to noted archaeologists Ernest Renan, Pierre Montet, and Maurice Dunand. Although some artifacts date from 6000 BCE and individual dwellings remain from 4500 BCE, the major public works are from 3200 BCE onward. The temple of Baalat Gebal (Our Lady of Byblos) began as a simple sanctuary surrounded by an enclosure. Over the years, this sanctuary grew in size and stature. Our Lady was regarded as Mother Nature and embodied love, fertility, and peace. As the goddess of love, her relationship with handsome, young Adonis in the hills above Byblos contributed to the legend of Aphrodite celebrated in Greek lore.

In Ugarit, Athirat/Asherah was similar in nature. But in clear contrast her companion, Anat, was a goddess of war who traditionally wore armor and carried weapons. The later Greek goddess who most resembled her was Athena, whose magnifi-

Baalat Gebal temple in Byblos. (Sanford Holst)

cent statues in Athens stood adorned in traditional armor.

—Sanford Holst

Notably, Ugarit was not a member of this affiliation. Although Byblos and Ugarit originally grew from Canaanite farmers and shepherds, Byblos and its daughter cities—Sidon, Tyre, Beirut, and others—developed the specific society that came to be identified as Phoenician. Ugarit remained Canaanite until its destruction in 1195 BCE. Ugarit had a king, but its use of a council has not been clearly documented. A council may have existed, however, since the religious beliefs of Ugarit included a principal god (El) who consulted with his divine council (Elohim).

The Greek Palace—Using Homer to Reconstruct Early Greek Government

In Book 1 of Homer's *Odyssey*, Telemachus (the son of Odysseus) anxiously awaits the return of his father from the dangers of distant Troy to his palace home on Ithaca. Telemachus knows nothing of his father's whereabouts or whether or not he is still alive, and he plots with his mother Penelope to keep the greedy suitors at bay until they can figure out what to do. After being inspired by the goddess Athena, Telemachus issues stern commands for the suitors to leave the palace of Odysseus. One of the worst offenders, named Antinous, responds, "I pray that Zeus will never make you king of Ithaca, / Though your father's crown is no doubt yours by birth" (1.443–444). Despite the comment by Antinous, the Greek word for "king" (*basileus*) does not imply hereditary rule by the monarch contained in the English word. In the Mycenaean world of Homer's epics, the monarchy is a government structure headed by a king proclaimed by public approval and superior talent, wealth, victory in

► THE PALACE OF ALCINOUS

Much of Homer's *Odyssey* takes place in the palace of Odysseus, but Homer's description lacks precision because of its focus on heroism. Visual details might be minimized because of the tradition that Homer was blind. Of any Bronze Age palace in Homer, the most fully developed description comes from Book 7, when the Phaeacian king Alcinous receives the ragged, storm-tossed traveler Odysseus. Homer describes Odysseus as brought to a standstill by the enormity and splendor of the palace of Alcinous. Odysseus steps over a bronze threshold to behold the "high-roofed halls" with walls plated in bronze and crowned with a frieze of lapis lazuli. The palace features doors made of solid gold, silver doorposts, and a lintel with statues of golden dogs surrounding the entryway. There is a large main room with two thrones backed against the wall, indicating an equal political status for Alcinous and his wife, Arete. Each throne is draped with "finely spun brocade," the work of Phaeacian women known for their skills with the arts of weaving. The palace is framed with "outer gates" for protection and courtyards surrounded by a "magnificent orchard four acres deep" and with a vineyard. The trees in Alcinous's orchard are pomegranates, pears, apples, figs, and olives that yield year-round because of the westerly wind.

—Jonathan L. Thorndike

battle, and landholdings, not strictly by heredity. In Book 8 of the *Odyssey*, the king of the Phaeacians (Alcinous) declares, "There are twelve peers of the realm who rule our land, / Thirteen counting myself" (8.435–436). The statement by Alcinous implies that the 12 peers are all kings affirmed by public approval, and he is a "first king" among equal monarchs.

Homer's *Iliad* and *Odyssey* are among the earliest written texts in Western civilization, dating from the eighth century BCE but referring to an earlier Bronze Age in which Mycenae was the most powerful Greek city-state. Homer chronicles the heroes of the Trojan War such as Achilles, Hector, Priam, Paris, and Agamemnon and their homecoming following a bloody ten-year conflict. King Agamemnon of Mycenae leads a

loose confederation of Greeks to extract revenge upon Troy for the theft of Helen, wife of Agamemnon's brother Menelaus, king of Sparta. The nature of Agamemnon's political authority is tenuous because kings from other Greek city-states complain about many of Agamemnon's decisions. The Greek city-states are independent from one another and ruled by local kings, but Homer does depict the beginnings of public debate and councils. When the Greek kings do not agree with Agamemnon's commands, they argue before each other and pass the scepter, which grants the speaker the floor. The debates do not have formal rules or clear lines of authority.

In the *Odyssey*, besides the palace of Odysseus, we also find partial descriptions of the palaces of Alcinous (king of Phaeacia), Nestor (king of Pylos), and Menelaus (king of Sparta). The *Iliad* is mostly the story of the closing days of the Trojan War, but the poem presents images of the palaces of Priam (king of Troy) as well as tentative accounts of the nature of Greek government. Both epics refer to Minos, legendary king of Crete, whose palace at Knossos was the most advanced early Greek society.

Heinrich Schliemann's excavations at Mycenae show that the Minoans influenced Mycenaean culture. Mycenaean civilization incorporated aspects of mainland Greek culture and adapted them to form a unique culture of its own. The Minoans had a more highly developed civilization and a more prosperous trading network than the Mycenaeans. The Minoans left their influence around the Mediterranean, where they sent ships with agricultural items and handicrafts. The Minoans left their influence on Greek culture with their frescoes, pottery designs, and palace architecture.

The Mycenaeans, in contrast, developed their own unique architectural style and political philosophy. At the top of their power structure, they probably used a patriarchal king, as did many Indo-European cultures. Evidence from Knossos suggests that the Mycenaean king may have been the head of a federation of rulers. In the *Iliad*, Agamemnon's status is based on a fragile political unity of mainland Greek kingdoms. Later archaeology has discovered actual Mycenaean records of bureaucrats and mayors of surrounding villages. These records contain tax

assessments, property descriptions, and catalogues of slaves, horses, chariots, and military regiments.

As described by Homer, the Mycenaeans developed a unique architectural style for their palaces. They knew about the mainland Greeks' use of the *megaron*. A *megaron* is composed of a series of rooms with a porch and inner rooms connected by a hallway. The Mycenaeans took the concept and placed it at the center of their largest palaces at Pylos, Tiryns, and Mycenae. At these three palaces, the *megaron* included a circular hearth in the center. The Mycenaeans also fortified their palaces with massive "Cyclopean" walls ten feet thick. The cut stones were so massive that later Greeks assumed that they could only have been lifted by a Cyclops, a one-eyed giant of enormous strength. The famous Lion Gate at Mycenae is embedded in Cyclopean walls. The gate inspired generations of artists who tried to imagine life during the Bronze Age in Greece.

Who Ruled the Minoans?

The presence of palaces on Crete since the Middle Bronze Age has led to the belief that some manner of ruler must have been present at least since the First Palace period. Sir Arthur Evans, inspired by the semidivine kings of the Near East, suggested that a priest-king ruled Crete and reigned over the island from his palace at Knossos. However, Minoan iconography contains no pictures of recognizable kings. Evans originally identified such a monarch in a reconstructed fresco from Knossos known as the Lily Prince

THE HARVESTER VASE

The Harvester Vase shows a group of males carrying what appear to be winnowing tools. One male has what looks like a rattle and has his head back and mouth open as if singing; perhaps he is the group musician. Another man with longer hair than the rest wears an elaborate shawl and carries a long staff over his shoulder. His costume and the length of his hair make him stand out as the older member of the group, most likely the authority figure in charge of the scene. The scene on the Chieftain Cup is a much simpler affair. A taller (perhaps older) youth with elaborate jewelry stands before a smaller (perhaps younger) youth wearing a helmet and carrying a sword over his shoulder. The older youth holds a long staff in his hand that he appears to be handing over to the younger fellow, whose hand is outstretched to receive it.

—Stephanie Lynn Budin

Fresco, which shows a striding male with an elaborate floral headdress (perhaps a crown) and jewelry. Since the original publication, though, it has been shown that the Lily Prince Fresco is actually an amalgam of three different frescos. The head with its fancy cap is actually the head of a sphinx. The two halves of the body—torso and legs—belong to females, which is evident from the white-painted skin (males were usually shown red). The torso belongs to either a boxer or an acrobat; the legs are actually walking in the opposite direction from the torso. The entire fresco would have been dismantled and reconstructed long ago if not for the fact that Crete's largest travel agency had already adopted it as a logo. Nevertheless, with the removal of the "prince," the Minoan repertoire suddenly became king-free. In its place, a new iconography of male authority figures was recognized. One example of this is a staff-bearing male recognizable on such Minoan items as the Chieftain Cup and the Harvester Vase, both from Hagia Triadha. The other is an axe-bearing "priest-king" prominent on Minoan seal stones.

The pose of holding out a staff appears frequently in the Minoan glyptic art (art engraved on seals), where deities hold such implements or hand them to humans. The use of this staff as a

divine symbol suggests that it has an authoritative meaning. In similar art from the Near East, deities often extend staffs to men to show their investiture with kingship. As such, it appears that in the Minoan art the staff is an emblem of either kingship or queenship or of the authority of the person holding it. For the Harvester Vase, the interpretation is fairly straightforward: the staff-bearing male is the leader of the troop. However, we have no idea if this translates into “king,” “priest,” or something else. Concerning the Chieftain Cup, Koehl has argued that the scene is the final act of an initiation ritual in which the young boy “graduates” to adult status in the community. Thus, the helmet and sword show the boy-turned-man’s adult status in the community, and the staff indicates either the authority of the male completing the initiation or the symbolic bestowing of power and authority onto the initiate. Once again, though, although the staff seems to imply authority, the type of authority (king, priest, etc.) remains open to debate.

An equally ambiguous figure is the axe-bearing male in the Minoan glyptic. This character, clearly an older fellow as indicated by him frequently appearing with a beard, routinely appears dressed in a distinctive wraparound outfit that goes from shoulders to feet, a much more elaborate affair than the usual Minoan male garb of a simple kilt. Sometimes this figure seems to be a deity, as he stands next to fantastic creatures such as griffins. Often, the seals depicting these men have a bull’s head on the reverse. As bulls were sacred in Minoan Crete, the males are interpreted as priests, and the bulls—or other animals they are shown holding, such as birds—are interpreted as sacrificial victims.

Some have suggested that the axe the man holds is similar to the later European scepter, serving, like the staffs, as an emblem of authority. If so, then we might have here a portrayal of Evans’s priest-king, a religious functionary who also wields some manner of secular power. However, as this figure never appears with other people, and as he is sometimes shown with fantastic creatures, it is difficult to tell if he is intended as a human at all or if he is a deity, possibly “imported” from the east where both his style of

clothing and axe were common. In the end, it is perhaps safest to suggest that the staff-bearing individual represents an authority figure in the Minoan repertoire, be it a deity or human, and the axe-bearing priest-king is a (perhaps divine) character in need of further study.

Of course, there is a certain irony to this search for the Minoan male authority figure, as most Minoan portrayals of authority figures were female. In fact, the notion of a Minoan matriarchy is still prevalent in some literature, although notions of *any* ancient matriarchies have now come under serious debate. Nevertheless, females, be they women or goddesses, do appear prominently in Minoan art, far outstripping males in most categories.

Amusingly, the most important datum in the search for Minoan royalty has no human portrayals in it at all. This is the throne in the so-called throne room of the palace at Knossos. This elaborately frescoed room has a fancy carved-stone throne attached to one of the walls. Griffins rest on either side of the throne. Evans originally believed that this was the priest-king’s seat and that the griffins’ presence confirmed that this king was somehow beyond mortal realms. However, parallels in Minoan art show that the character usually standing or seated between a pair of griffins was a female. Thus, it seems more likely that the person intended to sit on the Knossos throne was not a “king” but a “queen.” Of course, there are no easy answers in Minoan studies. The females portrayed between griffins, by the very fantastic nature of the griffins themselves, may have been goddesses. Who then, or what, actually sat on the Knossos throne? Perhaps the throne served as a seat for a deity, and no actual human sat there. Or, as is usually suggested, perhaps a priestess serving as a manifestation of a goddess sat on the throne during religious rituals. In such a case, did the Minoans have a priestess-queen instead of the priest-king? Or did they have a secular queen who used divine imagery to enhance her perceived power and closeness to the gods, as Medieval patrons had their portraits placed in paintings of the Holy Family? Such questions are not yet resolved.

In the end, we have little idea concerning who “ruled” the Minoans or even if any one per-

son did, king or queen. Tradition claims an especially important role for Knossos and its supposed king, Minos, but throughout Minoan history the other palaces were often just as wealthy as Knossos. Some have argued that all the palaces belonged to the king of Knossos, who used them as bases of operation throughout the island. Others have argued that there must have been several rulers on the island, each controlling his or her own territory through their personal palaces. The fact that neither the conquest of Knossos circa 1450 BCE nor its destruction around 1375 brought about the total downfall of Minoan civilization suggests that there was some independence among the different palatial regions and even independence among the cities and villas. It is entirely possible that the notion of monarchy did not even exist in Minoan society.

The Question of Leadership in the Indus Valley

One of the most vexing questions about the Indus Valley civilization (the ancient Harappans) is who were their leaders? The material culture of the ancient Harappans breaks with all of the patterns typical of urban societies from 4000 BCE to 1000 BCE. In an urban society, archaeologists typically expect to find symbols of leadership, markers of social inequality, and explicit displays of force (such as a monument depicting a military victory over an enemy group). Strangely enough, these markers do not appear in any great quantity, yet the Mature Harappan civilization lasted for over 700 years! So far, not even a palace has been located at a Harappan site, yet it is impossible to imagine that a sophisticated urban society could have existed for 700 years without leaders or conflict. Thus, scholars are

THE PRIEST-KING

The so-called "priest-king" making an offering to feed the sacred sheep, limestone cylinder seal, Sumerian, Uruk period, about 3500–3200 BCE. (Réunion des Musées Nationaux/Art Resource, NY)

A figure that appears as part of the shared material culture between Uruk and Susa from 3800–3100 BCE is the so-called priest-king. Depicted on carved plaques, cylinder seals, and other media, the priest-king appears bearded with his hair pulled back behind his hat and sometimes wearing a cap. He wears a skirt and is naked from the waist up. Often he carries a weapon (a bow, spear, or mace) and often attacks or asserts dominance over other figures. But who is this figure? Some suggest that this is an image of the ruler of Uruk and, by extension, the ruler of Susa and other parts of Iran. Others suggest that the priest-king image found at Susa reflects a local adaptation of Uruk symbols and refers to a local ruler. Others suggest that this is simply a generic figure of leadership that refers to no one individual in particular. Whatever the case may be, it does indicate a shared iconographic tradition between Iran and Iraq.

—Kevin M. McGeough

forced to reconstruct Indus Valley governance based on a lack of evidence. Be wary of any scholar who discusses this topic with any certainty; there is not enough evidence to make any strong claims about who the leaders were or how the government operated.

Some candidates for symbols of leadership have been noted. A figure called the priest-king by scholars appears in the artistic repertoire of the Indus Valley. Clay tablets with processional

scenes (individuals marching holding what appear to be standards), such as those found in contemporaneous Mesopotamian sites, have been found. The best evidence for some kind of political or bureaucratic apparatus are the numerous seals and stamps that have been uncovered. Our inability to read Harappan prevents us from being able to understand how these seals would have functioned. However, if they worked anything like they did in Mesopotamia and Egypt, these would have borne an individual's name or title and would have been used in the day-to-day operation of various government activities, standing in for an individual's signature or functioning as a personal or official seal of approval.

The settlement patterns of the Indus Valley may also give some clue as to ancient Harappan governance. The four major centers (so far identified) in the Indus Valley are quite far apart from each other. Harappa and Mohenjo-daro are over 388.4 miles (625 kilometers) apart from one another. This has suggested to many scholars that each of these large cities was an independent city-state, controlling a surrounding hinterland. Most sites, including smaller villages, are located along major river routes, thus indicating participation in a larger trade network.

Some degree of local governance is the most plausible reconstruction of Indus Valley governance at present. However, some scholars still maintain that the Indus Valley civilization may have been organized at the level of the state. These scholars argue that the uniform material culture (especially architectural styles, weights and measures, language, and art) suggest that there was a higher degree of organization. However, a shared material culture does not necessarily reflect a centralized political system. At present, though, the question of Indus Valley leadership must remain unanswered.

Jomon

The islands of Japan used to be joined to the Asian mainland by a land bridge connecting what is now Korea and Japan. Scholars assume that the earliest population of humans in Japan moved there across this land bridge. By about 11,000 BCE these early settlers had developed into the society that is identified as Jomon, and scholars talk about a Jomon period that lasted until about 400 BCE. Over this long time span a great amount of change occurred, which makes generalizing about this period difficult. The subsistence basis of the Jomon was not agriculture but rather hunting and gathering. However, the traditional image of this type of society has to be applied with caution to the Jomon. The climate and natural vegetation of Japan meant that hunting-gathering was relatively easy; this was especially the case because of the abundance of marine life (fish and shellfish) in the rivers and along the seacoast. Initially the earlier settlers had hunted large mammals, but as these started to become scarce, they switched to smaller mammals such as deer and wild boars and then to even smaller ones such as rabbits and squirrels at least in some areas. Even though hunting for meat remained a feature of Jomon diets, it is clear that fish and shellfish were key elements in Jomon nutrition. This in turn had a very important consequence; the Jomon people created settlements that seem to have been basically permanent. They did not move from place to place like typical hunter-gatherers because it was not necessary. This sedentary style of hunting and gathering is comparatively rare but was successful in Japan.

Settling in one place had a number of important consequences, some of which are verified by scholars and some of which can only be theorized. First and most famously, the Jomon people developed pottery. The term “Jomon” means “cord,” and the period has this name because of the corded design often used in their pottery. They were among the first groups in the world to develop pottery. Their pots served various practical purposes, but they were also richly decorated with clay designs applied to the outside of the pots. Many of them were also quite large. Because the Jomon were not nomadic, they

could develop such skills. Also, they were not concerned about moving their possessions from one place to another, and thus they could have more of them. Further consequences were the development of permanent houses, both pit dwellings and longhouses. They also needed burial sites, and it seems that special places were set aside for this purpose and used continuously over long periods of time. Of course, permanent or at least semipermanent settlements required refuse sites as well, which have provided very interesting knowledge of the Jomon. While the Jomon civilization is believed to have begun on the southern island of Kyushu, as the climate changed and the line of hardwood forests (Beech and Oak) advanced the Jomon people moved northward, gradually forming settlements throughout Japan. There is evidence that Jomon settlements allowed for the elaboration and specialization of certain crafts, which encouraged extensive trading between settlements.

While there is no such thing as a typical Jomon settlement, the site at Sannai Maruyama in Aomori in the far north of Japan gives research-

ers some idea of what the Jomon civilization was like at its height. This site appears to have been occupied continuously for more than 1,500 years (from about 3500 BCE to 2000 BCE), and occupation was probably year-round. While less than half of the site has so far been excavated, more than 500 pit dwellings have been found along with a number of large longhouses. Not all of these would have been occupied at the same time. There was also a large six-pillared building whose purpose is unclear: perhaps it was a shrine, or perhaps it was a watchtower. In addition, they built roads in their settlement by flattening the earth. This indicates a fairly high degree of civil cooperation and perhaps the existence of a stratified society similar to those that developed in agricultural societies. This means occupational specialization (farmers, craftsmen, etc.) and perhaps some type of ruling group. The people produced a large number of things including pottery, stone and bone tools, baskets, and jewelry. They also traded for jade and obsidian with other settlements 300–400 miles (500–600 kilometers) away. Their food consisted of

➤ WHERE DID THE JOMON PEOPLE GO?

Jomon culture was replaced by Yayoi culture over a few hundred years. Yayoi culture became the basis of the traditional culture of Japan. But what happened to the Jomon people? This is far from being an academic question. Yayoi culture clearly came from outside of Japan (especially Korea), but does this mean that there was a mass migration, making these migrants dominant not only in terms of culture but also population? Or was the culture adopted (and adapted) while the population remained the same? Put simply, who are the ancestors of the modern Japanese, or what happened to the Jomon people? Many Japanese people believe that the culture was adopted but that the population continued on to become the modern Japanese. Others believe that the Jomon people were either completely absorbed or pushed to the margins to become a minor element in the genetic makeup of the modern Japanese or even perhaps the ancestors of the Ainu people of Hokkaido. Modern scientific evidence seems to indicate that Jomon people contributed far less than the Yayoi migrants to the genetic composition of the modern Japanese. But much more work is needed, and the final answer may never be known.

—Michael Thompson

meat, fish, fruit, and nuts. Jomon pots were used to reduce salt from seawater so that some early method of preserving food was also possible. There were large numbers of chestnut trees in the area that they used extensively, as they could cook the chestnuts in their pots, thus removing acidity and softening them at the same time. All of this had social consequences as well. Softer food was good for both older people, who had difficulty chewing, and babies. In turn, this probably meant that Jomon people could extend their life expectancy to some extent as well as wean babies earlier and thus have more children. Mortality was still high, however, and the site has large numbers of burial jars, which were probably used for the burial of children.

The Jomon culture, then, was a relatively complex and sophisticated society, though it still suffered from some of the limitations of the hunter-gatherer lifestyle. It persisted for so long

because it was successful. However, this should not be overestimated: at its height, there were probably only 250,000 inhabitants of the whole of Jomon Japan. Eventually, beginning in Kyushu again, the advantages of agriculture became more obvious, and the Jomon were replaced by the Yayoi. However, despite the triumph of agriculture, elements of hunter-gathering persisted in Japan (especially in the mountain areas) until the twentieth century.

Tribal Governance in the Americas

The governing practices of prehistoric peoples in the Americas during the Archaic are unknown, although some inferences can be reached based on ethnohistorical, paleodemographic, and archaeological data. Generally speaking, it is assumed that the majority of prehistoric Americans were egalitarian in their political organization until population levels, certain mass resource exploitation practices, and sedentary patterns coalesced, at which point the governing structure changed to one based on ranked societies or chiefdoms. In regions where chiefdoms only partially emerged, such as the Plateau and Plains, tribal governing practices are thought to have been based on a combination of egalitarian and chiefdom-level practices. In this mixed political organization, certain individuals are thought to have been heads of bands or subbands who were members of regional intertribal councils that served some duties in intertribal matters or in resolving issues between bands. Based on paleodemographic and ethnohistorical data, it is hypothesized that the bands seasonally varied in size and that intertribal meetings took place on a seasonal basis. This was primarily because many of their activities would most likely have functioned more efficiently when bands came

together to cooperatively exploit seasonal resources such as anadromous fish runs in the Platteau or the congregating buffalo during the summer months in the Plains. At this level of political organization, leadership roles were most likely also designated for various activities such as wars, hunts, and ritual ceremonies in which individuals acted as task group leaders for specific occasions based on seniority and expertise rather than as permanent political leaders.

For example, on the Plains, evidence indicates that the basic social units of prehistoric peoples during most of the Archaic were extended families organized into seasonally nomadic bands or semisedentary villages, each independent but related to others speaking the same language and sharing the same culture. Paleodemographic evidence indicates that the political integration of bands or villages into larger tribal units was tenuous and incomplete, although social scale was an important variable in forming alliances, as smaller groups were more easily united than larger ones.

On the Northwest Coast, the prehistoric people of the region apparently governed via a ranked society, which was slightly different in that rank at the band level was more formalized and politically structured. However, the large-scale regional organization found in chiefdoms was lacking. In ranked societies such as those found during the middle to late Archaic on the Northwest Coast, social hierarchies were carefully measured and evaluated according to genealogy, wealth, and prestige. The social differentiation and individual political power depended in part on control over social exchanges of wealth within and between communities.

Chiefdoms, on the other hand, were more complex and based in larger forms of tribal governance than the egalitarian social groups of the Great Basin, Plains, and other regions or the ranked societies of parts of the Northwest Coast, California, the Southwest, and the Eastern Woodlands. A chiefdom is generally defined as a centralized polity that organized a regional population in the thousands but is smaller in size than a state. The distinguishing characteristic between a ranked society and a chiefdom was permanent institutionalized leadership patterns, which have been identified as belonging

➤ THE RANGE SITE

The Range site, located in the American Bottom segment of the central Mississippi River valley of southwestern Illinois, shows clear evidence of a Middle to Late Archaic chiefdom. Covering more than 25 acres, the site contained more than 5,500 features, including over 600 prehistoric structures. Evidence indicates that during the Late Archaic, the site consisted of a large village of more than 200 domestic structures that had nucleated from previously separate villages. The configuration of structures, the construction of large courtyards and plazas, and other spatial divisions at the site indicates that the Range site represents an early chiefdom where social ranking was clearly defined. By circa 950 to 1000 CE, evidence indicates that the larger area was under the political control of an emergent chiefdom that controlled the flow of resources up and down the Mississippi River for some distance.

—Peter N. Jones

to either simple or complex chiefdoms. The former had only one subordinate political level, while the latter had two or more subordinate political levels that were typically associated with geographically discrete central settlements. Chiefdoms encompassed the territorial and political control of a chief under which lesser chiefs controlled smaller areas. As such, chiefdom territories were often surrounded by unoccupied or sparsely occupied lands, sometimes called deserts, that were natural barriers and political buffer zones that often corresponded to linguistic differences. Evidence in settlement patterns from the Mississippian region, for example, indicates that between the large centers such as Moundville in Alabama and Etowah in Georgia existed relatively depopulated zones of forest.

Many different theories have been advanced to explain the existence of chiefdoms (also called nonstate complex societies). Explanations of the appearance or decline of chiefdoms have historically emphasized the relations between a society's resource base and its social organization. For example, evidence from the Ohio Valley indicates that social complexity and agricultural intensification increased during the Late Archaic,

resulting in the formation of regional chiefdoms. This evidence indicates that there is a strong association between social complexity and agricultural intensification in the formation of chiefdoms for this region. Likewise, in the Southeast the development of chiefdoms is often associated with the shift to large-scale maize agriculture around 1,200–600 years before the present. Among the best known of the prehistoric Southeast chiefdoms that reached considerable size were the Natchez, Coosa, Calusa, Apalachee, and Cofitachequi chiefdoms.

A proxy means of establishing the type of tribal governance in place in prehistoric societies is through the measurement of material wealth, which is a good indicator of prestige. Prestige is important because it indicates access to resources, which indicates the level of political organization in a particular society. For example, in the political sphere, chiefs have more prestige than common individuals because they have more material wealth. As such, competition for

prestige often results in the emergence of larger chiefdoms because there is a drive to constantly acquire more material wealth. Some archaeologists have argued that sufficient conditions for the emergence of chiefdoms are competition for prestige and a large enough population level to produce a sizable economic surplus, which must be under central control.

■ Introduction: The Development of States

The first states emerged during this period, but they were not the formalized nation-states that characterize political life today. For the period before 1000 BCE, archaeologists use the term "state" (or better, "early state") very loosely to refer to relatively complex civilizations that exhibit certain features. Population density is the most important feature; societies considered to be early states typically had populations of greater than 20,000 people. Not all of these people lived in cities, but cities played a more important role in state-level societies than in other types of societies. There are usually cities that wield significant power within the civilization politically, economically, or religiously. We can often distinguish the central places in early states. These central places typically have large public architecture, such as temples or palaces, that make them relatively easy to identify.

Leadership in early states varies considerably, but it was usually centered on the authority

of a king or the equivalent of a king. This individual was seen as the basis of legal life within the society and was empowered to enact laws that did not typically have to be cleared by other decision-making bodies. Likewise, policy decisions and relations with other polities were based on the whims of this leader. The king was almost always male, although there are some notable exceptions to this in ancient Egypt. How the king came to power varies in ancient states. Dynastic succession was very common and typically the most stable means of passing on leadership. Kings also came to power through violent uprisings, brought on by unclear succession policies or by weakened or unpopular leadership. Typically the king had a monopoly on force within the society, but practically this required an army with specialized military leaders (i.e., generals), so it was important for the king to promote loyalty among these generals. Since powerful officials in early states were not simply relatives of

the king (as was often the case in ancient chiefdoms), loyalty could not be guaranteed.

Society in early states was extremely stratified. People were divided into various ranks, classes, or statuses. The vast majority of people were understood to be living on land owned by the king and thus owed tax or military obligations almost as a kind of rent. There was no sense, as in modern North American society, that taxes were paid for infrastructure or social services. Taxes were the private wealth of the king to do with as he saw fit.

One of the most interesting questions that scholars ask about the age is how these states first arose. That they did arise in Egypt, Mesopotamia, and China is unquestioned. The mechanisms through which they arose, however, are far less clear. Ancient historical accounts of the origins of states are often shrouded in myth, seeing the origins of the state in the heroic actions of a legendary king or in the decisions and whims of the polity's gods and goddesses. This topic shall explore some of the evidence for the formation of early states.

—Kevin M. McGeough

The Rise of the Egyptian State

Ancient Egypt poses a unique problem for ancient historians, as it developed a unified government over a relatively large geographic extent significantly earlier than other locations, such as Mesopotamia, Syria-Palestine, India, and China. Why this occurred seemingly so quickly and what the mechanisms for the emergence of the first state where are questions that are debated by scholars yet are fundamental to understanding statecraft from a world historical perspective. It is likely that the agricultural productivity of the Nile Valley facilitated this (as large agricultural surpluses were possible in Egypt), but this has often been overemphasized in reconstructions of the rise of the Egyptian state. Early Egyptologists, such as Flinders Petrie, argued that the Egyptian state arose through the efforts of an invading race that conquered the dwellers of the Nile Valley and imposed a state structure upon them. There is no evidence for this, however, and current scholarship sees the emergence of the Egyptian state as an indigenous phenomenon.

Tradition holds that Egypt consisted of two conceptually distinct regions: the northern delta (Lower Egypt) and the southern floodplain (Upper Egypt). This division of upper and lower is apparent in the earliest iconography of kingship and remained throughout the duration of the ancient Egyptian state. Older models of the rise of the Egyptian state took King Narmer (Menes) as one of the earliest Egyptian kings who unified north and south through an act of military conquest. That warfare played a role in the unification of Egypt is suggested by the iconography of kingship. Three ceremonial artifacts excavated from Hierakonpolis (the macehead and palette of Narmer and the macehead of King Scorpion) depict the king as victorious in warfare and wearing regalia of both the southern and northern kingdoms. Subsequent finds, such as inscriptions in the western desert, likewise indicate the importance of warfare in the conceptualization of the early state. However, archaeological research suggests that the actual rise of a unified Egyptian state was significantly more complex than this.
